1 Preface

This document describes the simulation model of a platform capable of running a release of Linux cross compiled for the MIPS 32-bit architecture.

It provides a guide to running a Debian Linux Operating System release on the virtual platform.

The document was written using the Debian *Jessie* release which is based upon the Linux kernel version 3.16

1.1 Related Documents

This platform model uses peripherals from the OVP library. Consult the OVP library at www.ovpworld.org for documentation for the status on individual models. The device vendors should be consulted for individual device datasheets.

The processor cores are developed using the MIPS32 reference material available in general from <http://www.mips.com/products/product-materials/processor> in particular the documents:

- MIPS32® Architecture For Programmers Volume I: Introduction to the MIPS32® Architecture
- MIPS32® Architecture For Programmers Volume II: The MIPS32® Instruction Set
- MIPS32® Architecture For Programmers Volume III: The MIPS32® Privileged Resource Architecture
- Malta™ User's Manual

2 Introduction

The MIPS Linux platform, based on the MIPS Malta™ development board, contains models of hardware components to a sufficient level of accuracy to run the Linux operating system. The Debian distribution of Linux is provided as an example kernel with other files that are used in conjunction with the platform to show Linux booting.

The platform can make use of any MIPS32 processor model that provides the MMU requirements of Linux. The default processor model configuration provided in this platform is the 4KEc device. The MIPS32 4KEc is a 32-bit CPU with a Memory Management Unit with user- and protected-mode instructions to support a Virtual Memory Management System. Other 32-bit MIPS32 cores can also be specified, these include the 24Kc, 24KEc and 34Kc (which is shown booting SMP Linux). To see all the cores available look at the MIPS32 processor page in the library documentation of an OVP installation.

The MIPS32 models available from OVP and used in the Malta platform have been verified as part of the **MIPS-Verified™** program.

As well as running the provided Linux kernel the platform is intended to allow the ease of development of the Linux kernel, Linux user applications, Linux loadable kernel modules, additional platform components and porting other Linux distributions.

OVP provides base intercept technology allowing the ‘semihosting’¹ of native host features.

Imperas provides additional intercept technology, and modules using it to provide assistance with Linux on the Malta platform. Imperas also provides multiprocessor and platform debug capabilities.

2.1 Platform Definition Files

The platform is defined and downloaded as part of the standard OVPSim download. This is available in source form from the download section of the website www.ovpworld.org.

When installed the platform is defined by the module source found in

`IMPERAS_HOME\ImperasLib\source\mips.ovpworld.org\module\MipsMalta\1.0\module`

And the shared object loaded that is loaded by OVPSim in

`IMPERAS_HOME\lib\IMPERAS_ARCH\ImperasLib\mips.ovpworld.org\module\MipsMalta\1.0`

¹ Semihosting is a specific form of interception that is applied to low level functions in the C library being used. These function such as open, read, write etc are intercepted to give Host native operation using the Host file system.

The platform is described on the OVPworld website at

<http://www.ovpworld.org/library/wikka.php?wakka=Mips32MaltaLinux>

2.2 Demo Package Installers

The examples described in this document are available from the OVPworld website. They are described at

<http://www.ovpworld.org/library/wikka.php?wakka=Mips32MaltaLinuxBootInstructions>

From this page you will be able to download all the files you need to run the examples described.

There are three installations:

1. Demo_Linux_MipsMalta
2. Demo_Linux_MipsMalta_Install
3. Demo_Linux_MipsMalta_Disk

When installed a new directory will appear as

`IMPERAS_HOME\Demo\Platforms\Linux_MipsMalta`

When Demo_Linux_MipsMalta is installed this directory includes a copy of the module hardware definition, the Linux kernel 'vmlinux', a pre-built ramdisk 'initrd.gz' and scripts to execute.

By adding Demo_Linux_MipsMalta_Install additional install scripts are provided to control the download of the Debian Linux Kernel and the initial ramdisk file (initrd.gz) to provide the capability to perform a full install.

By adding Demo_Linux_MipsMalta_Disk a pre-built disk image containing a full Debian installation is provided, this can be booted from using the scripts installed by the previous installer, this package contains only the disk image.

3 Virtual Platform Command Line and Standard Usage

The MipsMalta virtual platform is executed by the *harness.exe* program that loads the module defining the hardware component and structure. It includes a standard command line parser that supports all the arguments supported by the simulator.

The command line parser is used to specify the specific use and also to configure components in the platform by overriding parameters. The following three tables provide the information required to execute the virtual platform simulation.

3.1 General Simulation Arguments

Argument	Value	Description
Modulefile	module/model.<ARCH>.so	Load the shared object definition of the Malta platform (so on Linux or dll on Windows)
variant	4Kc	Specify the processor variant configuration for the processor model
Verbose		Enable verbose simulator output
Output	imperas.log	Specify a logfile to write simulator output
wallclock		Run simulation at a maximum of real time
objfilenoentry	vmlinux-4.9.30-4kc-malta	Load the kernel image into memory but does not alter the PC of the processor

3.2 Specific Configuration Override Arguments

These are all applied using `--override component/parameter=value`

Component	Parameter	Override Value	Description
Core_Board_SDRAM_promInit	kernel	vmlinux-4.9.30-4kc-malta	Specify the Linux kernel to load
Core_Board_SDRAM_promInit	initrd	Initrd.gz	The initial ramdisk file that is loaded into memory on the next page boundary after the kernel
Core_Board_SDRAM_promInit	command	console=ttyS0	An additional kernel command line parameter written into the start up table in memory
uartTTY0	console	T	Start a console attached to this UART
maltaFpga	stoponsoftreset	T	When the FPGA soft reset bit is written stop the simulation
PIIX4-IDE	drive0Name	Mipsel_hda	The file holding the hard disk image
PCI_NET	redir	tcp:15901::5901, tcp:11001::11001	Port re-direction allows external TCP/IP connections to be mapped into the simulation
vga	noGraphics	F	Disable graphics emulation

4 Board Architecture

The platform is illustrated by the following block diagram. It is architected to closely represent the MIPS Malta hardware in so far that

1. the binary image can be interchanged between the virtual platform and real silicon;
2. the software performs the same function on the virtual platform as it will on real silicon.

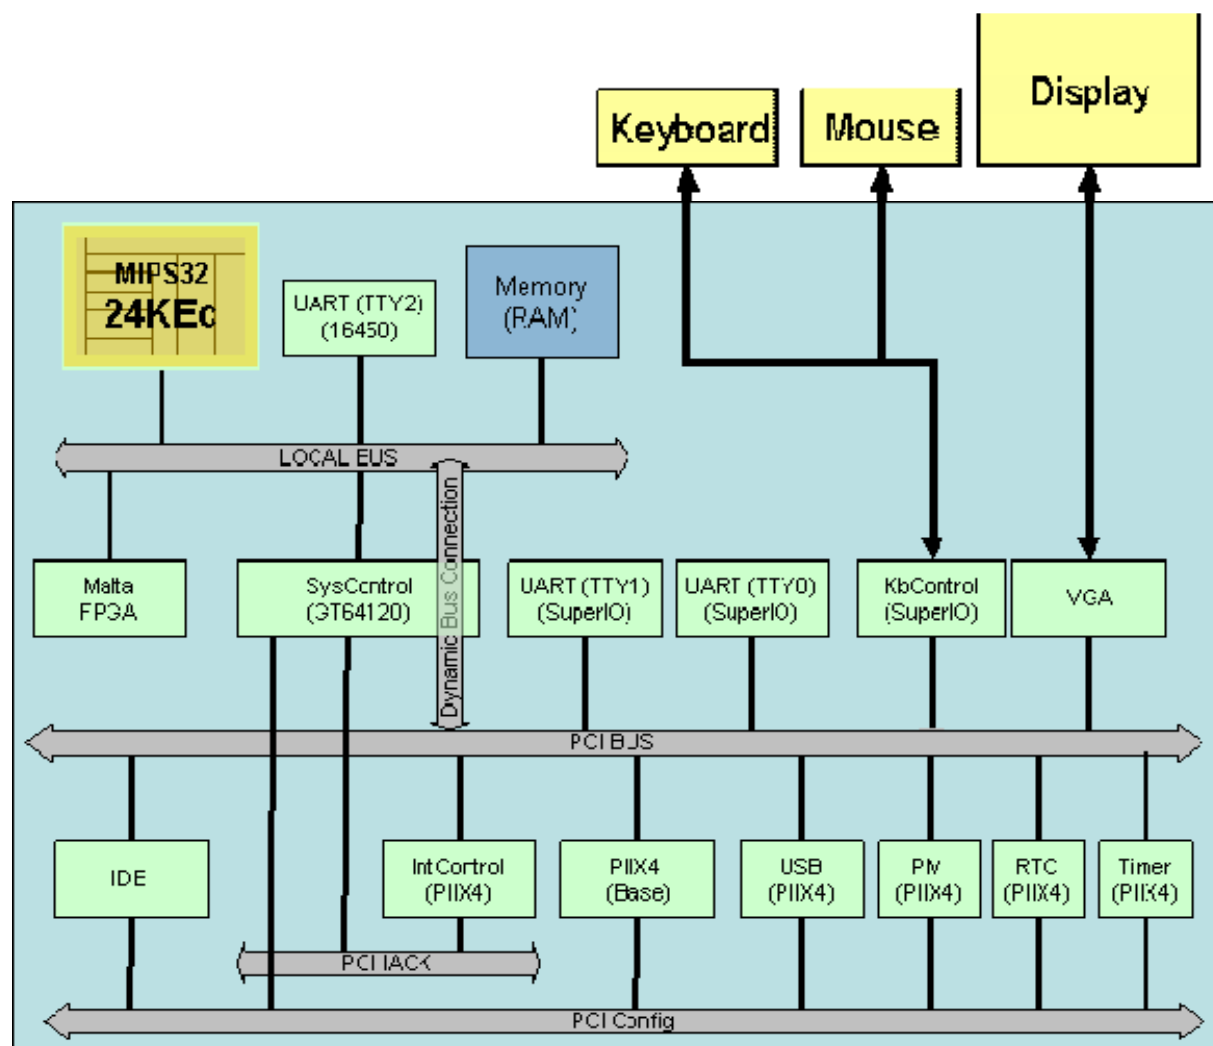

Figure 1 Platform Block Diagram

The CPU is connected to a local bus and a GT64120 general purpose system controller which supports SDRAM, FLASH and provides a bridge to an on-board PCI bus.

The PCI bus services a 4-channel IDE disk controller, a USB interface, AM79C973 Ethernet interface and a Cirrus CL GD5446 VGA graphics controller.

A bridge to an ISA bus supports a PS2 keyboard, mouse interface and two 16450 UARTs.

An FPGA specific to the MIPS Malta™ board controls an LED display, reads a set of switches and implements a third 16450 UART.

Two cascaded 8259 interrupt controllers, as part of the Intel PXII4E device, route interrupts from most devices to the MIPS32 int0 input.

The following diagram provides the general memory map of the platform. Some memory areas, such as the PCI memory and PCI IO regions contain a number of mapped devices.

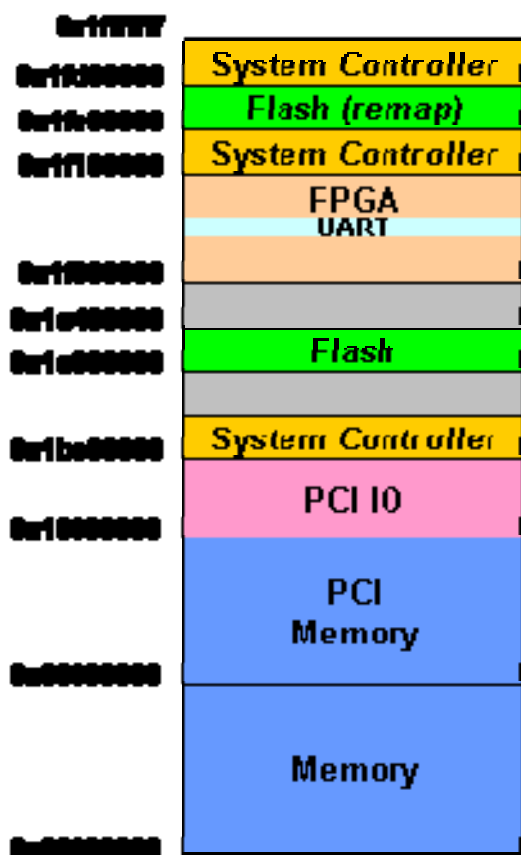

Figure 2 Basic Platform Memory Map

5 Malta Peripheral Models Overview

This section is intended to provide a brief overview of the operation of the peripherals that can be configured and details of the parameters that may be used within the virtual MipsMalta platform to change behavior. For complete descriptions of the peripherals the OVP documentation should be consulted.

5.1 SmartLoaderLinux

The Linux SmartLoader is created as a peripheral but is used in the simulation to initialize the platform. It is capable of providing all configuration information required by the Linux kernel. This includes the kernel command line being created and written into memory, and boot options; that is boot from a hard disk image or boot from an initial ramdisk.

Parameter	Platform	Model Default	Description
kernel	vmlinux	None	specify the linux kernel being loaded (this must be specified)
envpaddress	None	0x80002000	change the address to which the kernel command lines parameters are based
initrd	initrd.gz ²	None	specify the initial ram disk that should be loaded for booting
root	/dev/hda ³	None	specify booting from the hard disk image eg /dev/hda1
boardid	None	0x420	Malta platform with CoreLV
memsize	None	128Mbytes	Set memory available to kernel
command	None	None	Allows additional kernel command line parameters to be added
nonelinux	None	None	Allows a none Linux kernel to be loaded and executed on the Malta platform.
bootimage	None	None	Replace the default reset vector code to change the manner in which the Malta system boots.

Table 1: SmartLoader Parameters

The SmartLoader will read the Linux kernel to obtain the highest load address and the *kernel_entry* symbol. The *kernel_entry* symbol is used to update the jump address in the boot loader and the highest kernel load address is masked with the TLB page mask for the load address of the initial ram disk file i.e. in the next page above the kernel.

Alternative boot code may be loaded by specifying the bootimage Parameter. This should specify a **.fl** file, as loaded via the parallel port on the actual hardware.

² Specify the argument 'initrd' on the command line when invoking the Malta platform to select booting from the initial ram disk initrd.gz. Without this argument the platform will boot from the file system on the disk specified by Drive0Name on the IDE model.

5.2 GT64120 (SysGT6412x)

This is a system controller providing an interface between the local bus and SDRAM and PCI buses. The model provides the PCI interface; including PCI configuration bus and PCI Interrupt acknowledge bus connections and access cycles. The model does not provide the SDRAM memory interface; this is provided as discrete memory in the platform.

Parameter	Platform	Model Default	Description
-----------	----------	------------------	-------------

There are no user definable parameters for this model

Table 2: GT64120 Parameters

5.3 Uart16450

This is a simple UART model for the 16450 devices. In this platform it can also be used to maintain a log of its output as well as providing it to stdout.

Parameter	Platform	Model Default	Description
outfile	None	None	Log the characters to the log file specified by this parameter.
infile	None	None	This file is used as input for the UART
registeralign	None	1	Allows the 8bit UART registers to be aligned on non-byte boundaries
log	None	None	The UART output is logged into the simulator stdout. There is no UART input.
portnum	None	None	Port number allows the connection to an external application

Table 3: UART16450 Parameters

5.4 PIIX4E (PciPIIX4Ebase)

The PIIX4E is modeled using a number of discrete component models such that the PIIX4E model itself contains only the base functionality that is common, for example the PCI configuration registers.

Parameter	Platform	Model Default	Description
-----------	----------	------------------	-------------

There are no user definable parameters for this model

Table 4: PIIX4E Parameters

5.5 IDE (PciIDE)

This is a simple IDE model, which resides on the PCI bus, allowing the connection of up to 4 devices. Each device is separately created as an image of the disk file structure. The model will attempt to open 3 drives, as specified below; if any device cannot be opened a warning will be generated.

If one of the devices contains the file system for booting the SmartProm 'root' parameter should be specified accordingly.

Parameter	Platform	Model Default	Description
PCISlot	10	None	Set the PCI Slot for the
PCIFunction	1	None	Set the PCI Function number
Drive0Name	mipsel_hda	None	The name of the file for the first drive.
Drive1Name	mipsel_hdb	None	The name of the file for the second drive.
Drive2Name	mipsel_cd	None	The name of the file for the third drive.
Drive3Name	None	None	The name of the file for the fourth drive.

Table 5: IDE Parameters

5.6 USB (PciUSB)

The USB model does not provide USB functionality. This model provides the PCI interface necessary to register the device and provides NULL data when any register is read.

Parameter	Platform	Model Default	Description
PCISlot	10	None	Set the PCI Slot for the
PCIFunction	2	None	Set the PCI Function number

Table 6: PIIX4 USB Parameters

5.7 Power management (PciPM)

The power management model does not provide power management functionality. This model provides the PCI interface necessary to register the device and provides NULL data when any register is read.

Parameter	Platform	Model Default	Description
PCISlot	10	None	Set the PCI Slot for the
PCIFunction	3	None	Set the PCI Function number

Table 7: PIIX4 Power Management Parameters

5.8 Interrupt Controller (IntPIIX4E8259)

The interrupt controller used in the platform is contained within the PIIX4E device but is modeled as a discrete device. It comprises of two individual Intel 8259 interrupt controller models that are cascaded.

A single interrupt is generated to MIPS32 processor, which in turn causes a PCI Interrupt Acknowledge cycle that provides a vector indicating the interrupting device with the highest priority.

Parameter	Platform	Model Default	Description
-----------	----------	------------------	-------------

There are no user definable parameters for this model

Table 8: Interrupt Controller Parameters

5.9 VGA (VgaCLGD54xx)

This model creates a Cirrus CL GD 54xx and utilizes SDL to create an output window to which the VGA is generated.

Parameter	Platform	Model Default	Description
PCIslot	18	None	Set the PCI Slot for the
scanDelay	50000	200	This is the rate at which the frame data is displayed (frame rate)
noGraphics	0	0	When set the SDL interface is disabled and no display is created.
Title	“OVPSim MIPS32 Malta”	“CL GD54xx”	This is the title displayed on the graphic screen

Table 9: VGA Parameters

5.10 PS2 Controller (Ps2Control)

The PS2 Controller uses SDL for mouse and keyboard input. It must be used in conjunction with the VGA peripheral device that generates the SDL output window with which it interacts.

The SDL interface supports polling only and so the PS2 Controller polls the SDL interface for activity on the mouse or keyboard. The poll rate is configurable.

Parameter	Platform	Model Default	Description
disableInput	0	0	When set this causes the input from the PS2 Controller to be disabled. This is used mainly for testing.
pollPeriod	50000	2000	The value provided for the poll period is the rate at which the PS2 input devices are polled for input. The value is in micro seconds.
grabDisable	0	0	Stop the mouse being grabbed when clicked in window

Table 10: PS2 Controller Parameters

5.11 Real Time Clock (RtcMC146818)

This is a model of an MC146818 real time clock device.

Parameter	Platform	Model Default	Description
timefromhost	0	0	When set this causes the current time to be read from the host during initialization.

Table 11: Real Time Clock Parameters

5.12 Malta FPGA (MaltaFPGA)

This is a model of the FPGA device that is available on the Malta platform.

Parameter	Platform	Model Default	Description
stoponsoftreset	1	0	If set when the soft reset register is written with a special value it causes the simulation to terminate.
switches	None	0	Set the value of the Malta 'switches' accessed by the FPGA

Table 12: Malta FPGA Parameters

5.13 Ethernet Controller (NicAM79C97x)

The Ethernet controller is a partial model of the AMD AM79C97xx series device.

It has sufficient capabilities to support a Linux operating system, specifically the Debian distribution of Linux 2.6.

In addition, it models a virtual Ethernet with a restricted bridge to the real Ethernet of the host (using the publicly available *SLIRP* package).

Specifically, the bridge emulates a DHCP server which allocates the NIC an IP address of 10.0.2.15 and performs Network Address Translation onto the host network of outgoing and incoming TCP and UDP packets. ICMP packets are blocked (so for example, *ping* does not work) and tftp requests are all handled in the model by a simple tftp server. Static address translations for can be set up for incoming requests on particular ports using the *redir* argument to the model.

Parameter	Platform	Model Default	Description
PCISlot	11	None	Define the PCI slot in which the Ethernet card is installed
PCIfunction	0	None	Define the PCI function of the device
ethereal		0	Packet logging using ethereal format
polldelay	1000	1000	The rate at which the network is polled
MAC	None	52:54:00:12:34:56	Define the MAC address of the NIC
redir	None	None	Specify and open ports on the simulated system. Example usage: 1. exposing gdb-server ports for attaching debuggers to user applications or 2. exposing a port for an ftp connection
tftpPrefix	None	None	Enable TFTP and define the tftp root on the host
localNet	10.0.2.0		Change the local network address

Table 13: Ethernet Controller Parameters

5.14 System bus, PCI bus, ISA bus

The Malta™ platform bridges a limited address range from the System bus to PCI bus and bridges a different range from PCI bus to the System bus. This allows the CPU to access part of the PCI address range and for PCI bus masters to DMA data directly into the main memory.

OVPsim models address spaces rather than physical busses. Therefore there is no bridge from PCI to system bus; all devices share the same address space. When a PCI device is programmed

to decode a particular address range, it adjusts the range according to the base address of the bridge. The net effect is the same, but the model can allow mappings which are not possible in the hardware.

Similarly, the ISA bus is not modeled explicitly; its devices appear on the PCI bus according to PCI configuration.

6 Booting the pre-built Linux Kernel

6.1 Introduction

The MipsMalta platform is designed to boot a Linux kernel from a number of sources. The Linux_MipsMalta demo provides everything necessary to boot a pre-built Linux kernel using a simple ram disk (also provided)

The Debian linux kernel is built for the Malta platform and the MIPS32 little endian device using a distribution available from Debian and can be found in the file named *vmlinux*. This image is built as a standard image and the same file runs on the virtual platform and the actual MIPS silicon device with real hardware.

Linux can boot from an initial ram disk file in a compressed form and extracted into simulated memory. This file is called *initrd.gz* and is provided as part of Linux_MipsMalta. It provides a basic set of commands using the BusyBox system with a minimal file system. As downloaded the initial ramdisk will boot to a shell prompt.

6.2 Linux Kernel Versions and SMP Support

This example is provided with a Debian distribution of the 2.6.23.11 Linux kernel.

The same platform has also been used with a Debian distribution of the 2.6.24 Linux kernel and a MIPS Technologies Incorporated distribution of the 2.6.29.4-1 Linux Kernel.

The MIPS32 processor model can support the MIPS single core processors, for example 4Kc and 24KEc and also the MP core processors, for example the 34Kc. The Linux kernel is built with SMP support enabled. Thus if an MP core supporting SMP is selected as the processor variant Linux will boot as SMP.

6.3 Execution Sequence

There is a specific sequence of events carried out by the OVP simulator and the ‘SmartLoader’ peripheral on startup.

6.3.1 Memory Initialization

The following memory initialization is performed:

- Debian Linux kernel image (*vmlinux*) is loaded directly into memory using addressing contained in the elf file by the OVP simulator.
- Bootstrap code is created at the MIPS processor reset vector by the “SmartLoader” peripheral component.
- A kernel command line is created in memory by the “SmartLoader” peripheral component.

6.3.2 Execution

Execution starts from the MIPS processor reset vector at virtual address 0xbfc00000. The generated bootstrap code resides at this address and performs some basic setup before a call into the Linux kernel, at the `kernel_entry` point.

6.4 Running the Platform

6.4.1 Booting from 'RamDisk' Initial RAM Disk

To run this demo obtain and install the Demo_Linux_MipsMalta installer for your platform from www.ovpworld.org. Go to the directory:

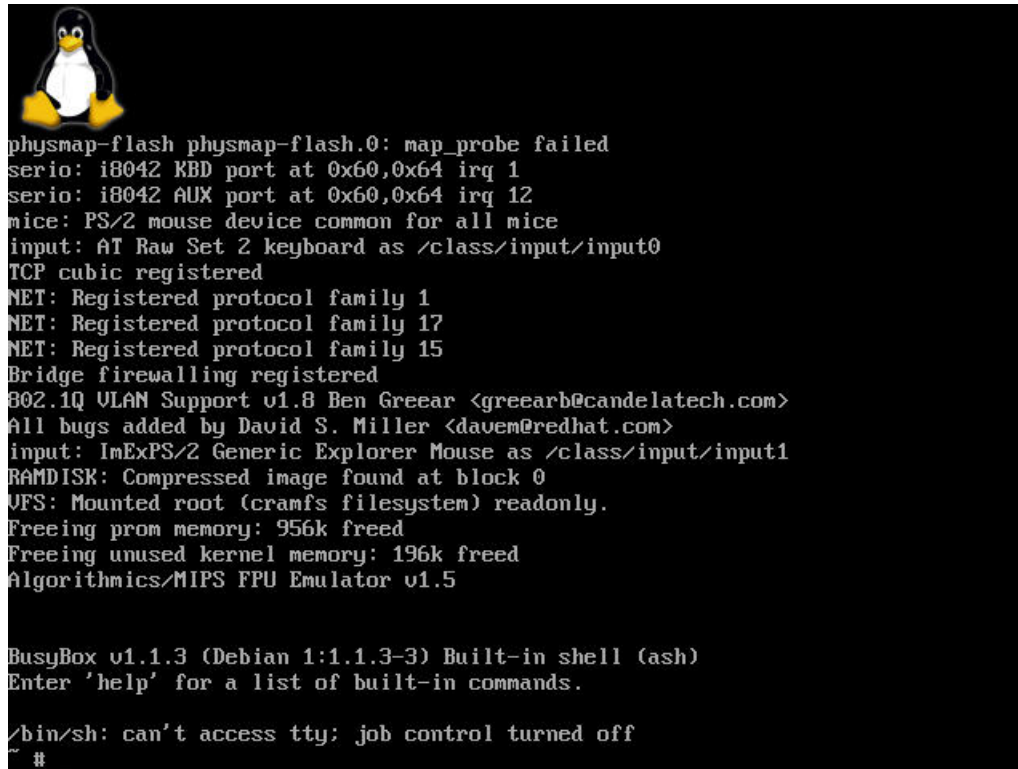

```
IMPERAS_HOME/Demo/Platforms/Linux_MipsMalta
```

and launch the simulation with the batch file 'RUN_MipsMalta.bat' on Windows or the sh script 'RUN_MipsMalta.sh' on Linux.

This will execute the platform executable passing in the Linux kernel as the first parameter and initrd as an additional parameter to switch the boot mode to initial ram disk.

The supplied initial ramdisk boots to a shell prompt.

The execution of the platform will commence until the shell is reached, as shown in Figure 3: Booting to Shell from Initial Ram Disk

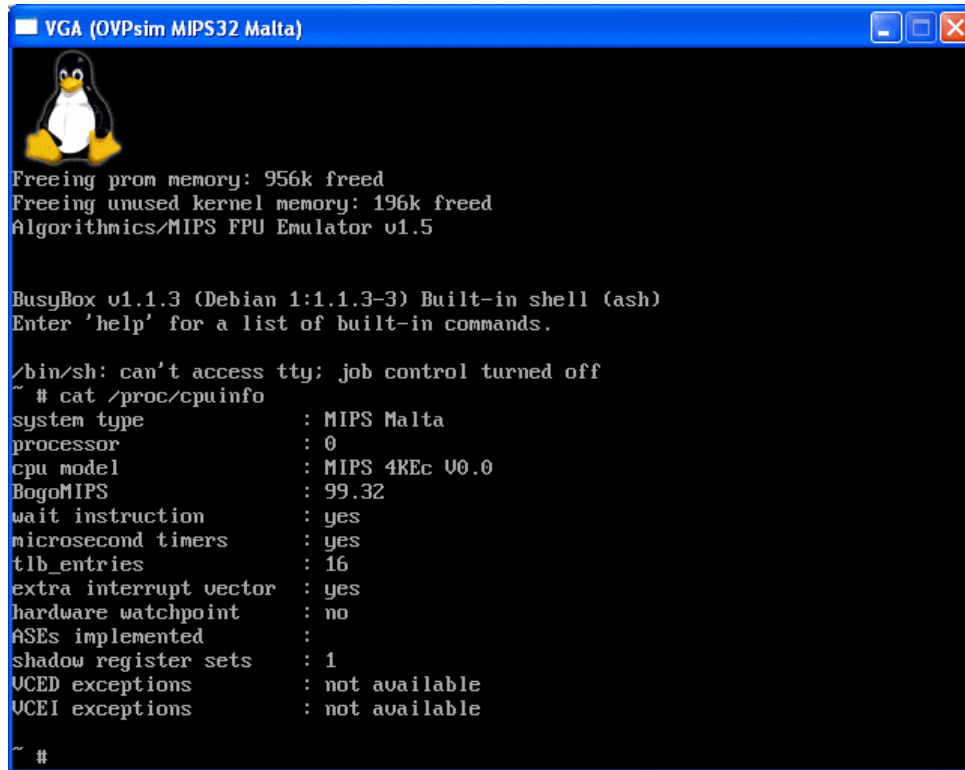

```
phymap-flash physmap-flash.0: map_probe failed
serio: i8042 KBD port at 0x60,0x64 irq 1
serio: i8042 AUX port at 0x60,0x64 irq 12

```

Figure 4: Shell Prompt

The simulation may also be launched with the batch file 'RUN_MipsMaltaSMP.bat' on Windows or using the sh script 'RUN_MipsMaltaSMP.sh' on Linux. This will select the 34Kc MIPS32 processor variant that supports SMP.

The execution of the platform will commence until the shell is reached, as shown in Figure 5: Booting to Shell from Initial Ram Disk (SMP)

The image shows a terminal window titled "OVPsim MIPS32 Malta". At the top left, there are two penguin icons. The terminal text shows the boot process: "physmap-flash physmap-flash.0: map_probe failed", "serio: i8042 KBD port at 0x60,0x64 irq 1", "serio: i8042 AUX port at 0x60,0x64 irq 12", "mice: PS/2 mouse device common for all mice", "input: AT Raw Set 2 keyboard as /class/input/input0", "TCP cubic registered", "NET: Registered protocol family 1", "NET: Registered protocol family 17", "NET: Registered protocol family 15", "Bridge firewalling registered", "802.1Q VLAN Support v1.8 Ben Greear <greearb@candelatech.com>", "All bugs added by David S. Figure 5: Booting to Shell from Initial Ram Disk (SMP)

6.4.2 Terminating the Simulation

We can terminate the simulator using CTRL-C. This should be done in the window from which the simulation was originally invoked i.e. not the simulated console window. Alternatively the simulated console window can simply be closed which will also terminate the simulation.

The two windows that will be present during the simulation are shown in Figure 6: Execution and Simulated Console Windows

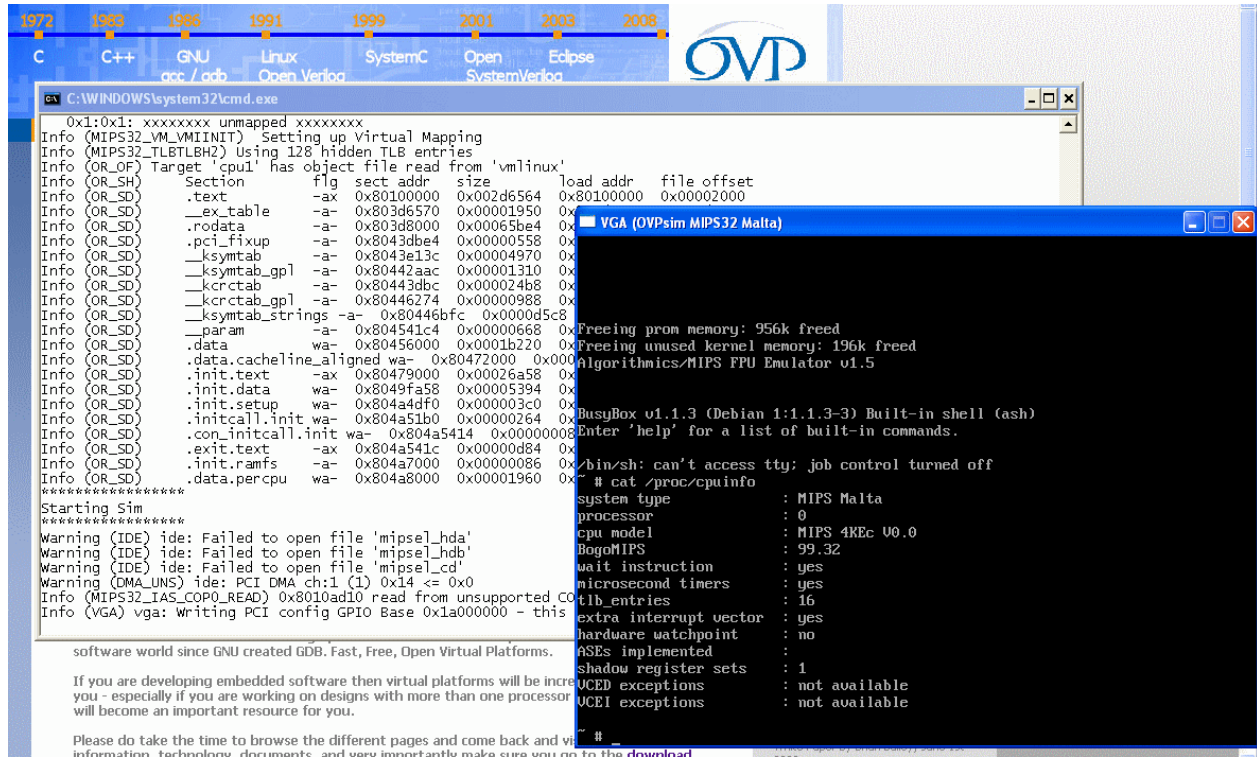

Figure 6: Execution and Simulated Console Windows

When terminated the simulator provides some final execution statistics that includes the instructions executed by the processor and the performance achieved, as shown in Figure 7a: Execution Statistics Output

```

7 Installing Full Linux Distribution

In addition to the simple preconfigured ram disk version described in section 6 the Demo_Linux_MipsMalta_install demo allows you to download and configure your own full Linux kernel in a simulated platform.

The supplied initial ramdisk allows you to perform a full Linux installation using a Debian Linux distribution site. This requires access to the internet from the machine you are running the simulation in order to download the required files for the Linux installation.

7.1 *Simulation Invocation Script*

Obtain the Demo_Linux_MipsMalta_install package from www.ovpworld.org and install it on your system. Go to the directory:

```
IMPERAS_HOME/ Demo/mips_MipsMalta_Linux_install
```

and launch the simulation with the script file 'RUN_InstallLinux.bat' on Windows or the shell script RUN_InstallLinux.sh' on Linux.

This will execute the platform, passing in the Linux kernel, specifying the ramdisk **initrd.gz** to set the boot mode and **--finishonhalt** to stop the simulation if a halt command is issued in the simulated kernel³. In addition the **--wallclock** option is selected so the simulation will not run faster than realtime, which can cause premature timeouts when accessing the internet through the semihosting interface..

7.2 *Creating an Empty Disk Image*

When the script is invoked you will first be prompted to enter the size of disk that should be created. This should be at least 1 Giga Byte.

Figure 9, shows the creation of a 4GB disk image.

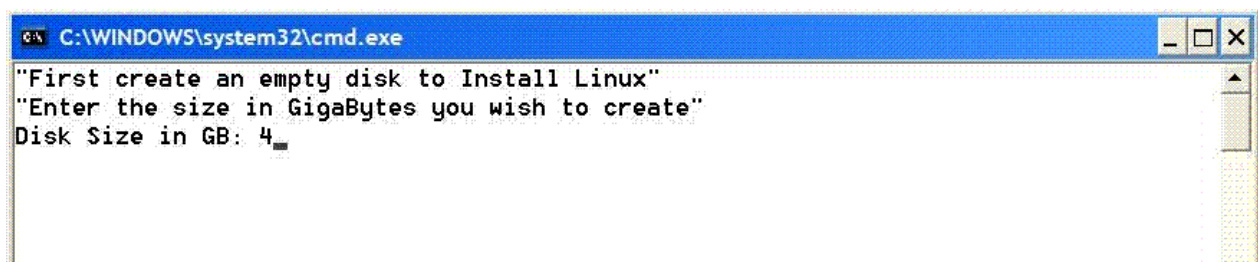

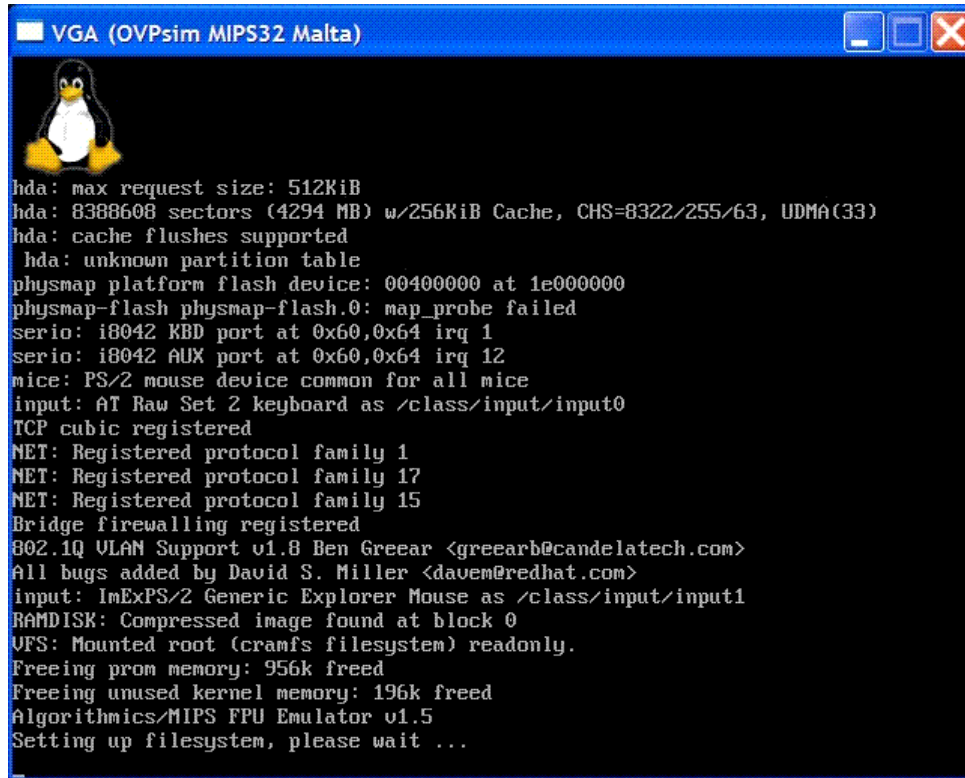

Figure 9: Create 4GB blank Disk Image

³ The halt command actually invokes a write with a special value to a register in the Malta FPGA. It is this write that causes the simulation to finish.

7.3 Starting the Linux Kernel Boot

Once the disk is created the script will start the simulation of the Malta platform. The initial boot sequence is the same as the other example, with the output from the kernel logged to the console as shown in Figure 10: Kernel Booting from Install INITRD:

```
VGA (OVPsim MIPS32 Malta)
hda: max request size: 512KiB

Figure 10: Kernel Booting from Install INITRD

7.4 Installing a Linux Distribution

A typical Linux installation is performed following the prompts of the graphical user interface provided by the VGA peripheral in the virtual platform.

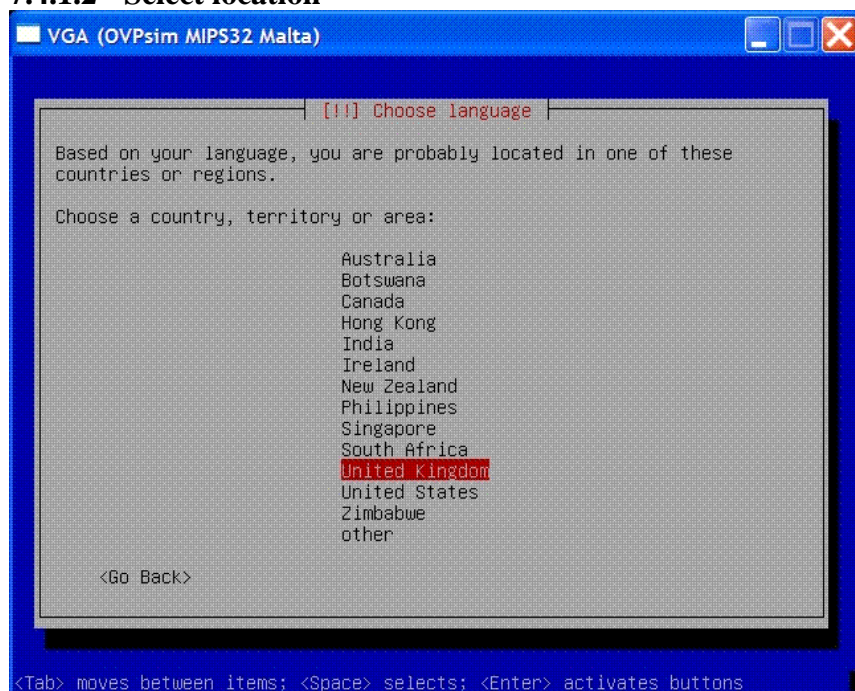

This section describes the full installation sequence. To complete a full installation will take around 1-2 hours.

7.4.1 Configure Local

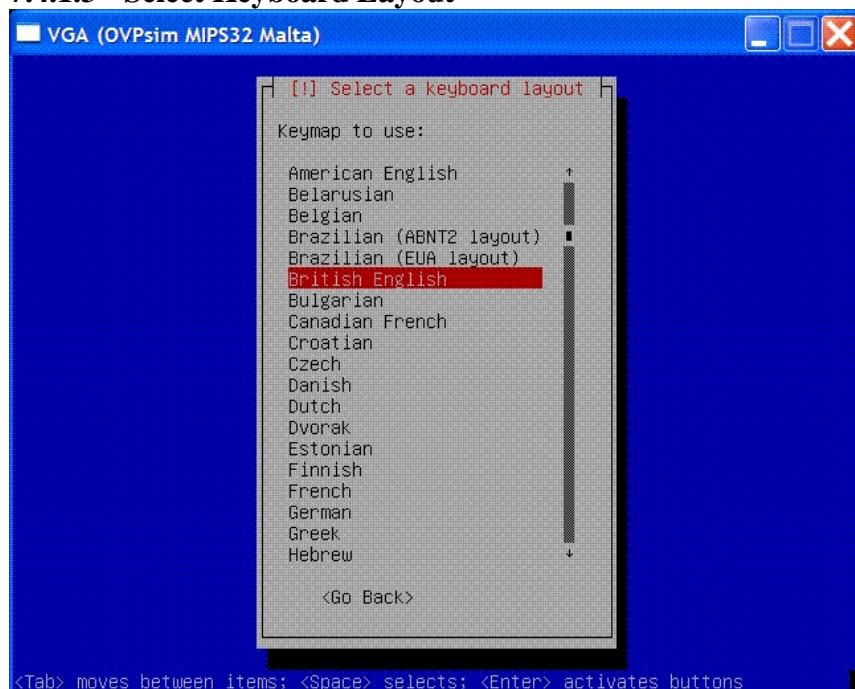

7.4.1.1 Select Language

7.4.1.2 Select location

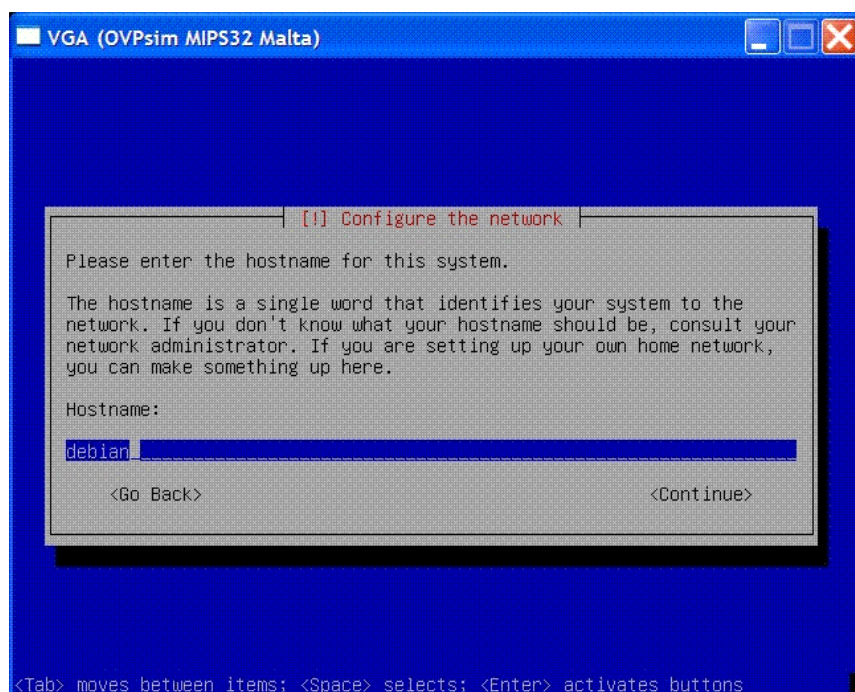

7.4.1.3 Select Keyboard Layout

7.4.2 Configure the Network

7.4.2.1 Select Host Name

You should choose a hostname that this installation will be known by. This will be the name that will be seen on your real network when running the simulation.

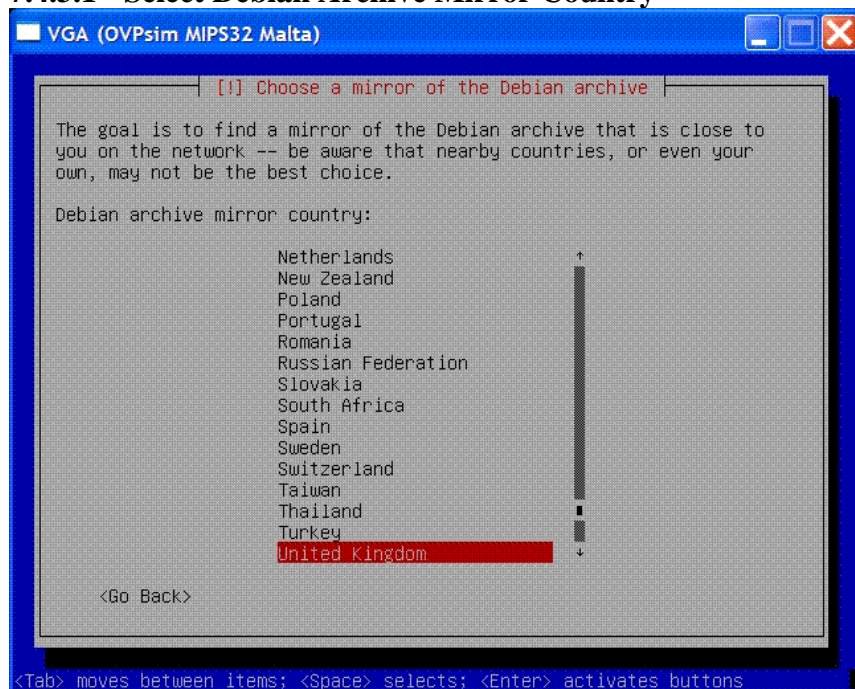

7.4.2.2 Select Domain Name

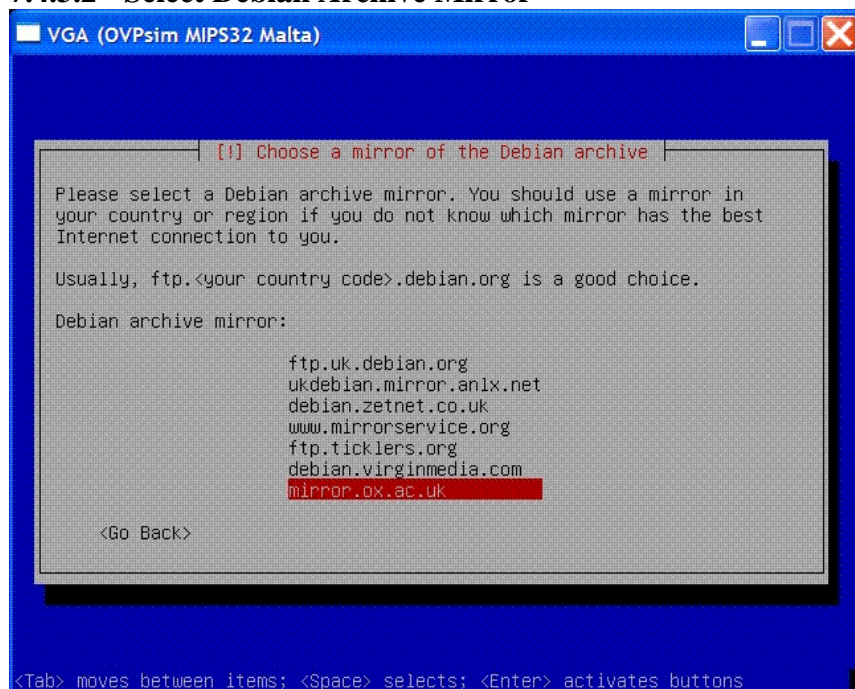

7.4.3 Download Debian Components

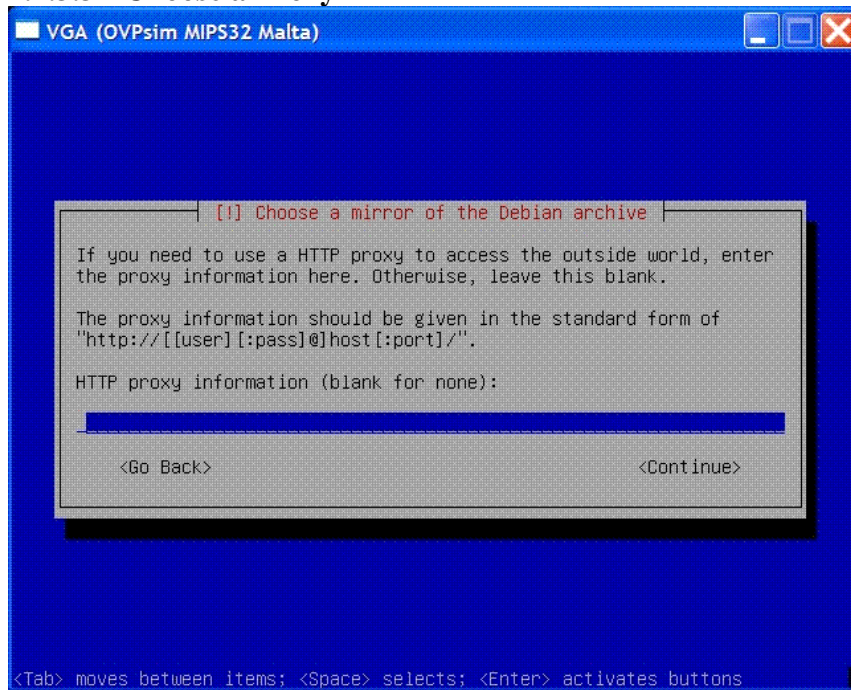

7.4.3.1 Select Debian Archive Mirror Country

7.4.3.2 Select Debian Archive Mirror

7.4.3.3 Choose a Proxy

7.4.4 Download Installer Components

7.4.4.1 Continue Without Kernel Modules

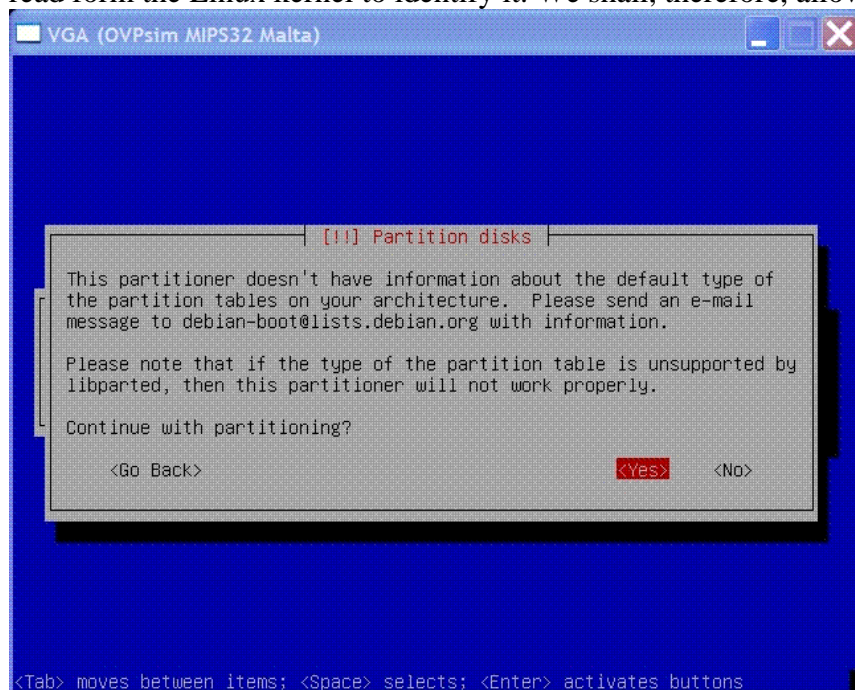

If prompted to continue without kernel modules, select **YES**. The kernel we are providing is built from the Linux 2.6.23 release. The distribution is not yet available at this release. This does not cause any problems for the installation.

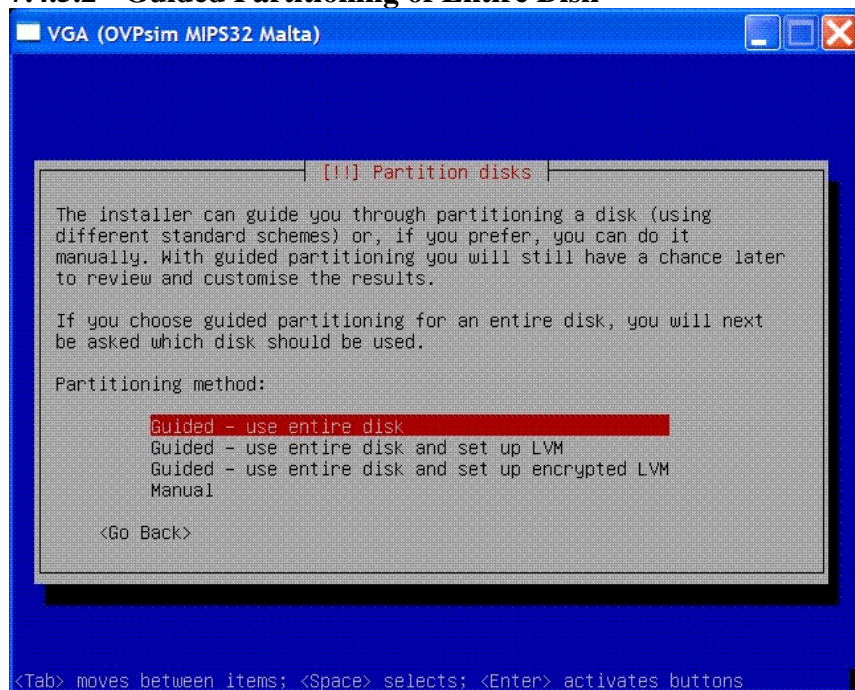

7.4.5 Partition Disk

7.4.5.1 Start Partitioning

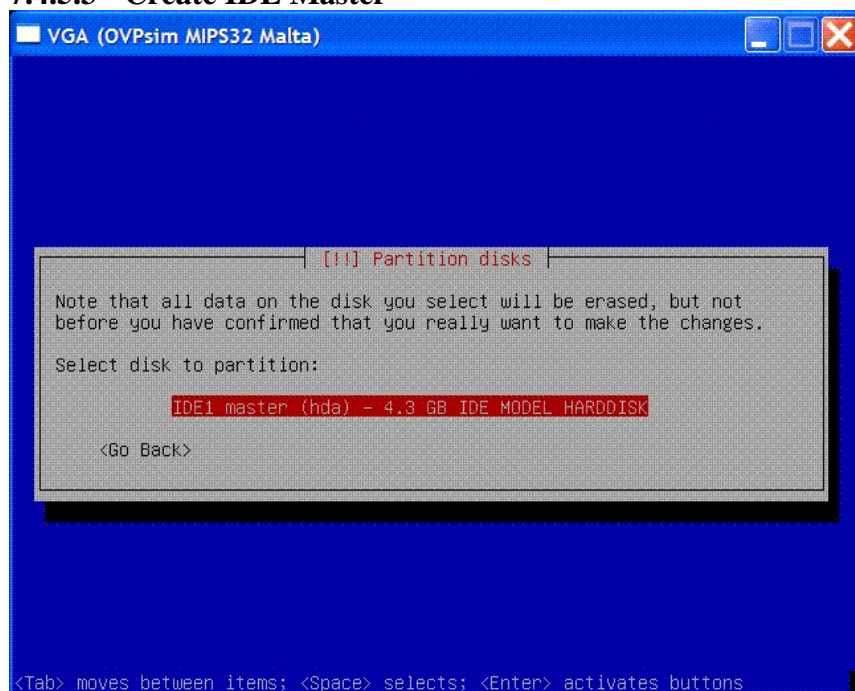

The initial disk image that we have created is blank and so contains no information that can be read from the Linux kernel to identify it. We shall, therefore, allow partitioning to continue.

7.4.5.2 Guided Partitioning of Entire Disk

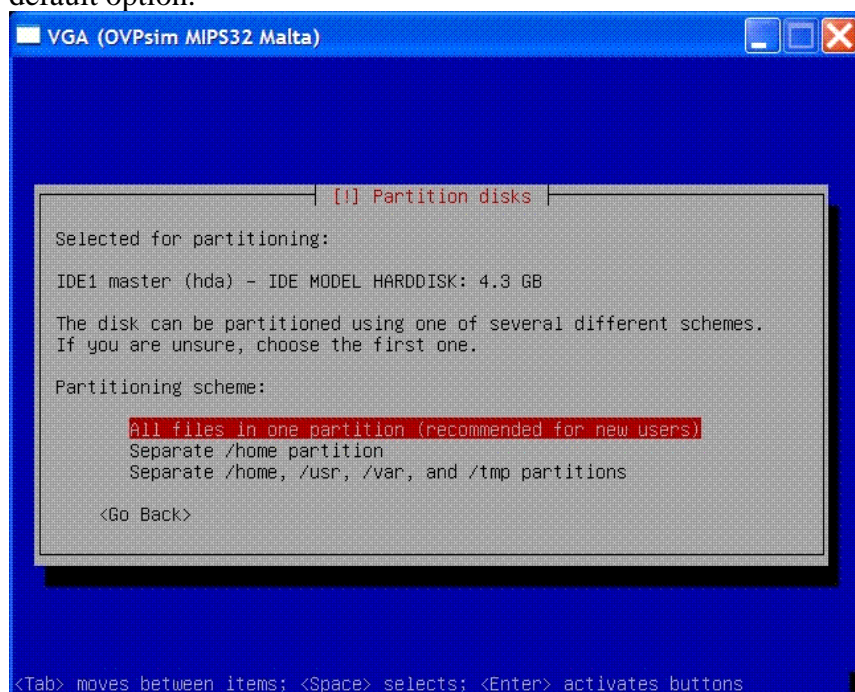

7.4.5.3 Create IDE Master

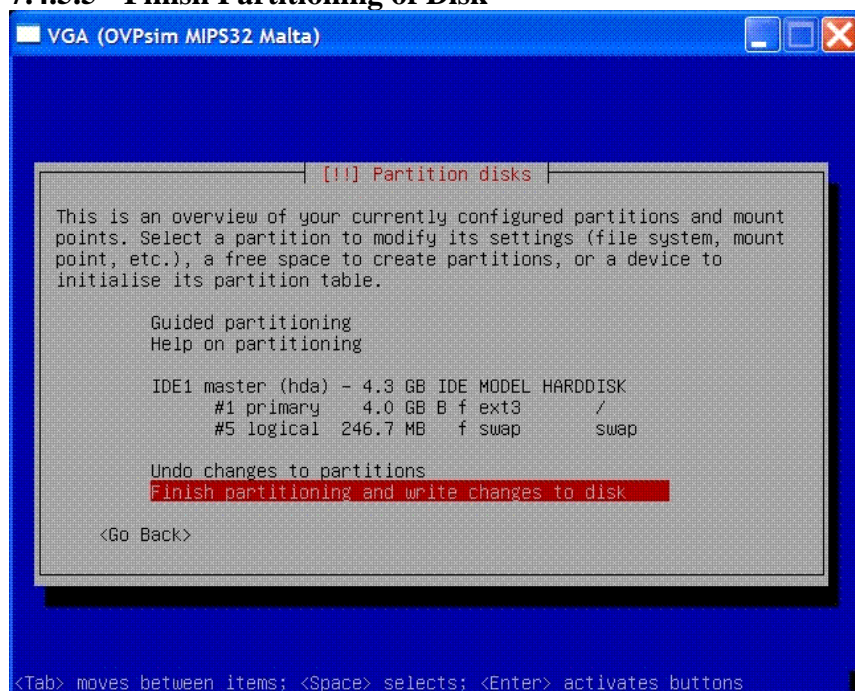

7.4.5.4 Choose Partitioning

Choose the partitioning of the disk. Unless you have specific requirements, please select the default option.

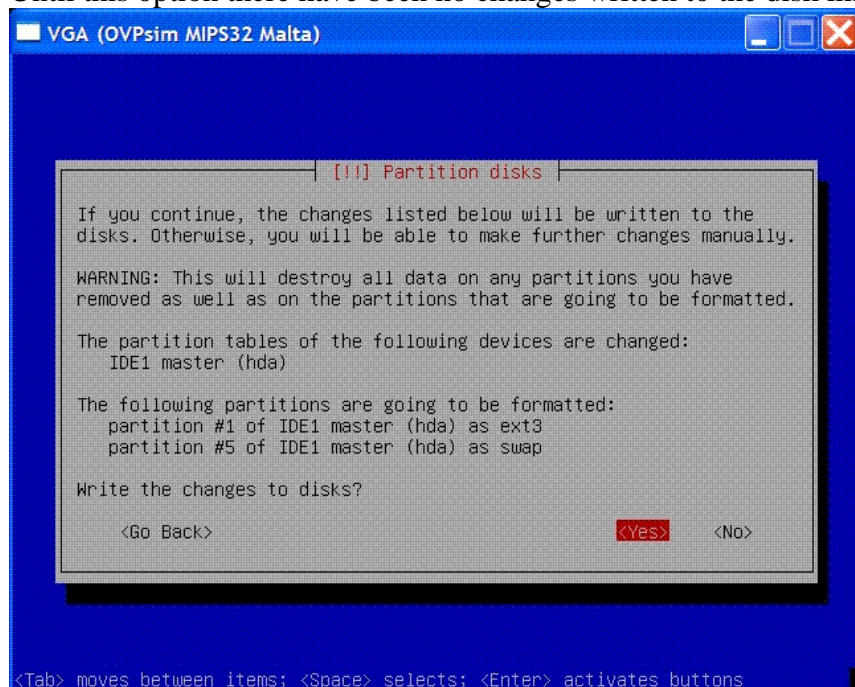

7.4.5.5 Finish Partitioning of Disk

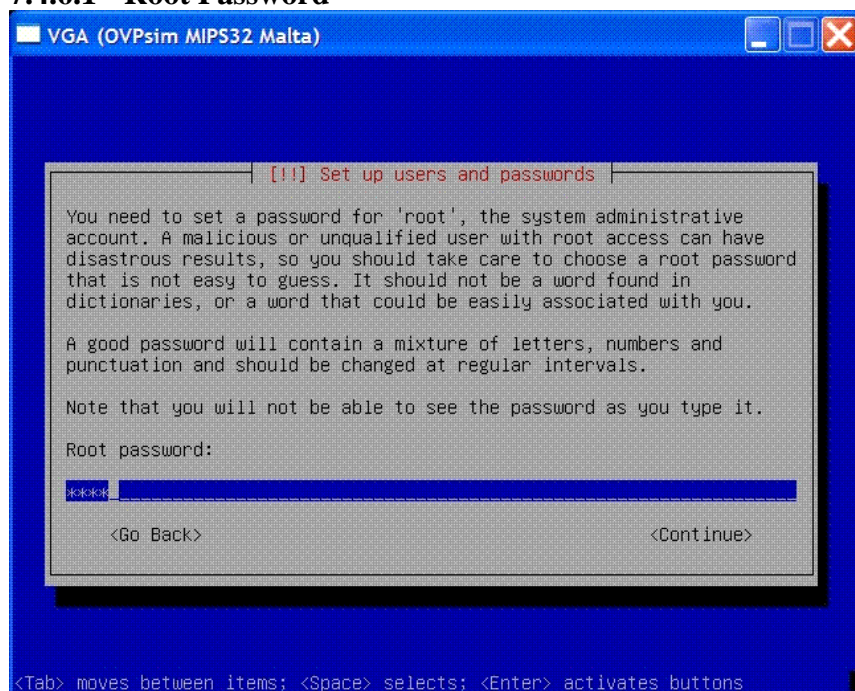

7.4.5.6 Write Changes to Disk

Until this option there have been no changes written to the disk image.

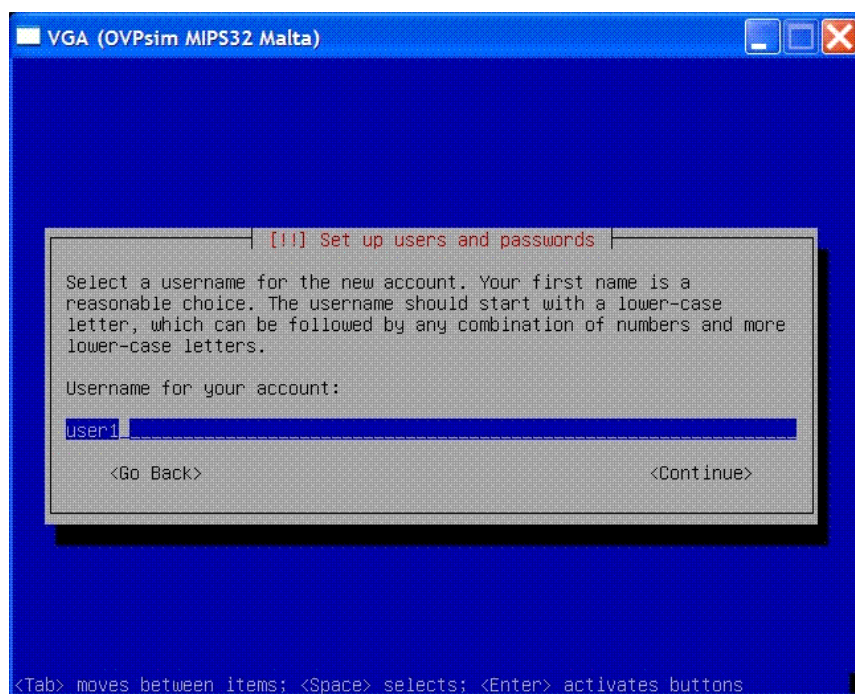

7.4.6 Setup Accounts

7.4.6.1 Root Password

7.4.6.2 Add User Account

7.4.7 Base System Installation

7.4.7.1 Verifying the Release

The installation of the base system will now progress.

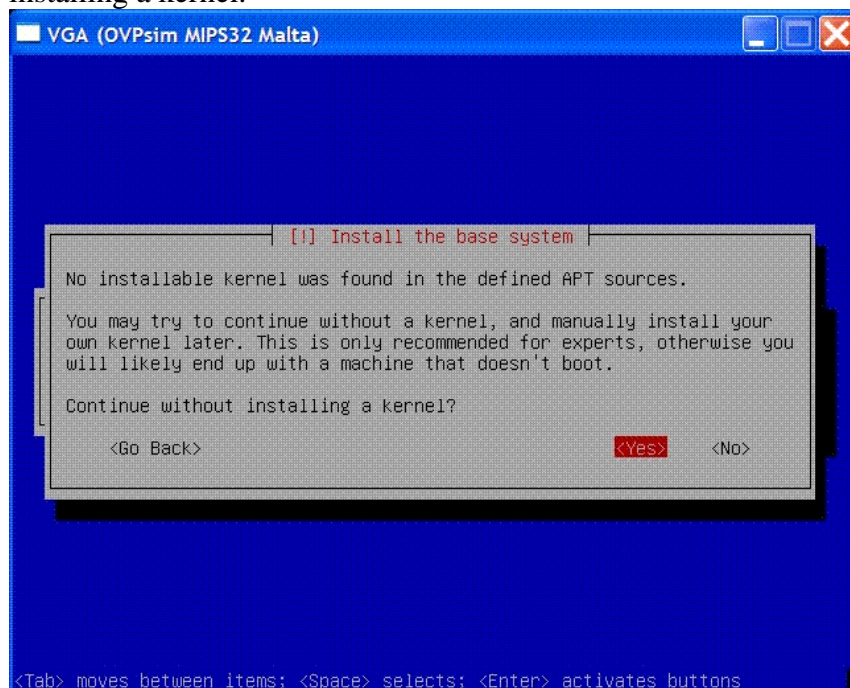

7.4.7.2 Retrieving Packages

This will take the longest period of time ...

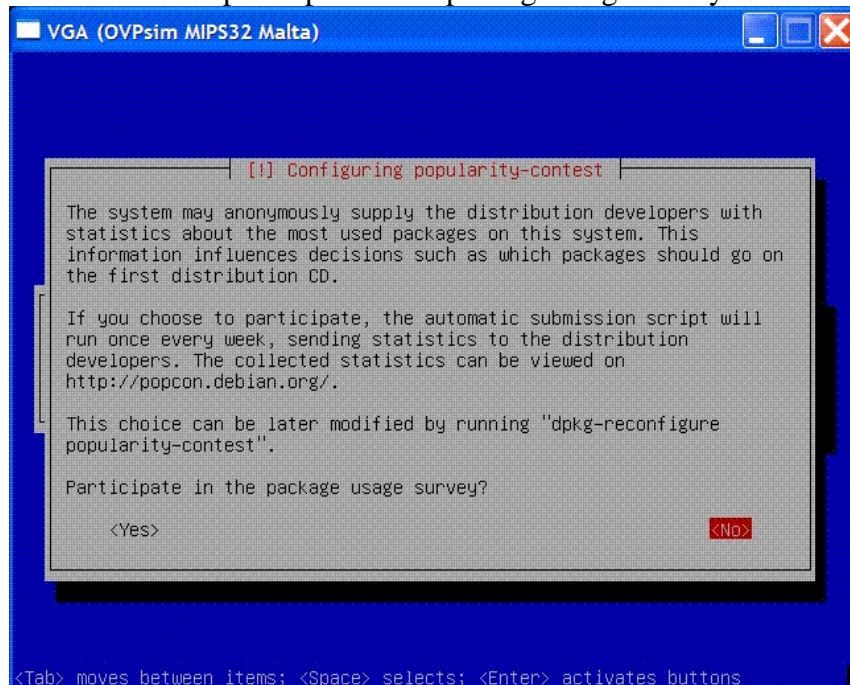

7.4.7.3 Continue Without Kernel

The Linux kernel is provided separately from the release. We, therefore, can continue without installing a kernel.

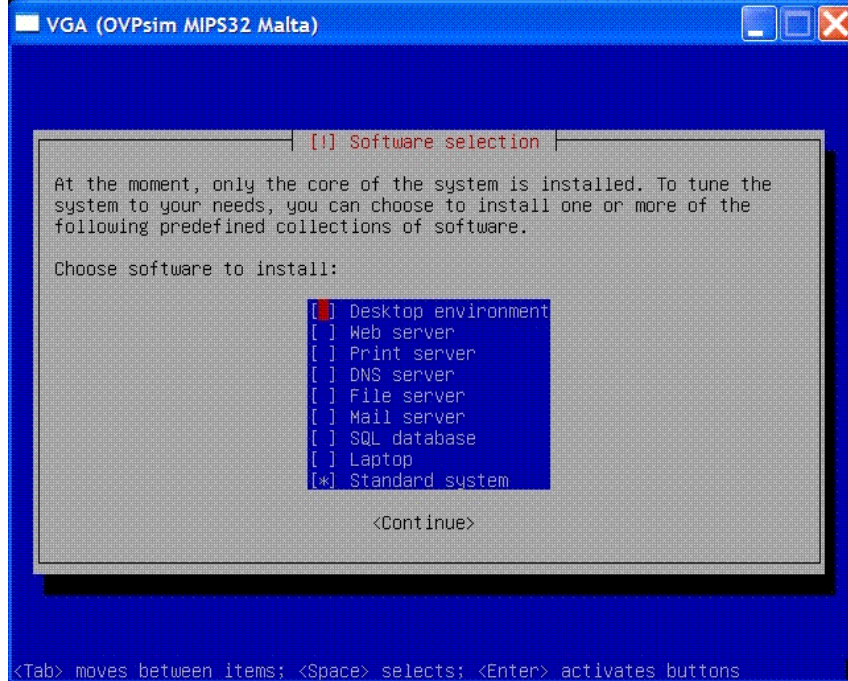

7.4.7.4 Package Usage Survey

Select NO to not participate in the package usage survey.

7.4.7.5 System Selection

The system selection determines the default set of packages that will be installed.

7.4.7.6 No Boot Loader

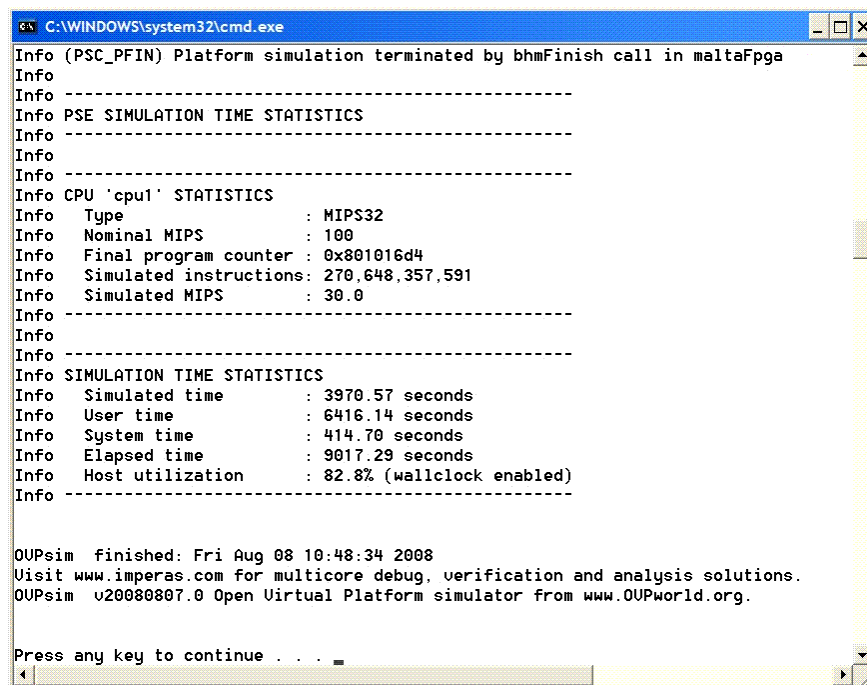

The boot loader is provided as part of the Malta platform, so continue the installation without it.

7.4.8 Complete Installation

At this point the installer will make a request to reboot the system. The simulation platform is set up so that it does not perform a reboot but finishes the simulation, with the statistics of the simulator run being displayed on exit.

7.5 Re-Start System

7.5.1 Boot directly from Disk Image

Run the platform by executing the batch file RUN_BootLinux.bat or shell script RUN_BootLinux.sh that is provided.

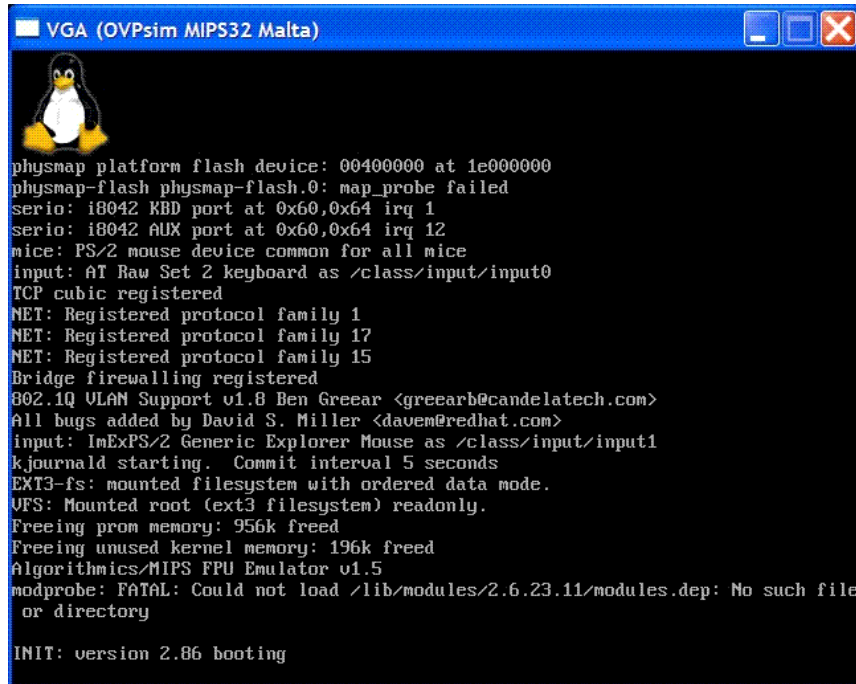

This will execute the platform in the same way as the previous script but will

1. omit the disk image creation stage, and
2. boot from the disk image rather than the initial ram disk

The kernel starts booting in the same way as before by detecting and configuring the hardware in the platform. The boot then continues from the disk image with the full Linux installation.

The file modules.dep is missing from the installation and so modprobe fails, this is expected because the kernel modules were not installed as part of the installation. These exist as a separate kernel image.

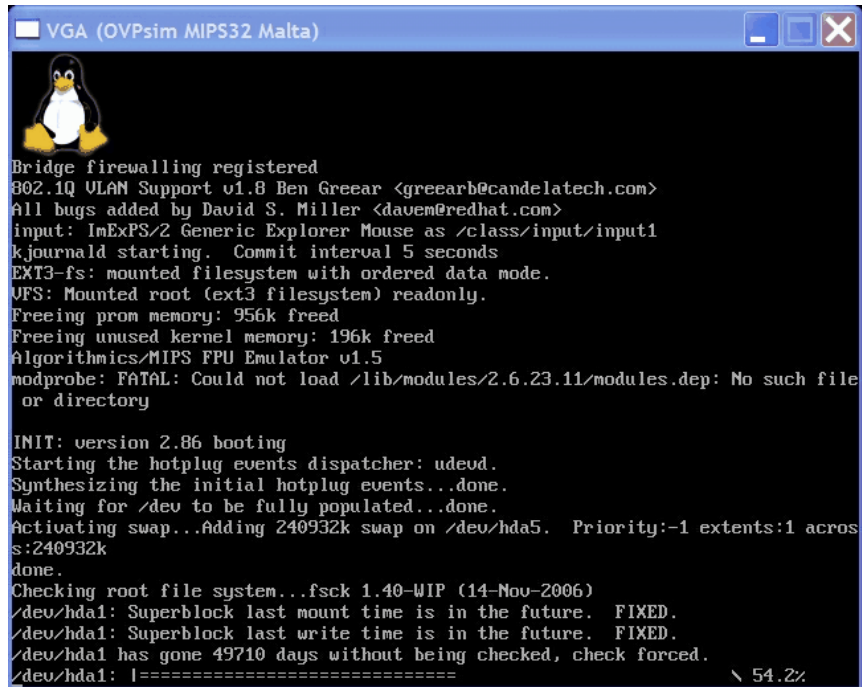

INIT boots the system ...

user1@debian:~$

```

7.6 Stopping the System

The disk image will be written by the disk controller at regular intervals. However, to ensure that everything on the disk is in the correct state the simulation should be stopped using the halt command when logged in as root. This will ensure all data is flushed to the disk image and that no corruption will occur. When logged in as root issue the command

```
> halt
```

The halt command, when used in conjunction with the *--finishonhalt*, argument will cause the simulation to stop. If the *--finishonhalt*, argument is not used you will have to CTRL-C the simulator in the command shell or close the VGA graphics display.

8 Disk Image Files and Initial RAM Disks

8.1 Introduction

The MipsMalta platform can be configured to boot from an initial ram disk or from a hard disk image, as has been shown previously in this document. This section provides some information on the creation and maintenance of these files.

A windows executable is provided to create a blank disk image or standard Linux tools can be used to create and modify the Linux disk images and initial ram disks used in the simulated Linux environment.

8.2 Hard Disk Image

A single file is used to encapsulate a file system as accessed by the disk interface of the PciIDE peripheral component.

By default the platform attempts to access three disks, mipsel_hda, mipsel_hdb and mipsel_cd. The main disk for booting will be mipsel_hda, a warning will be created if disks are not available.

8.2.1 Creation

An executable, create-image.<arch>.exe, is provided as part of the installation of **Demo_Linux_MipsMalta_install** to be used to create a blank disk image. This image can be accessed by the IDE controller model in the Malta platform and populated.

Alternatively the disk image can be created using standard Linux tools.

The following example command creates a disk image called 'newDisk' that is an empty file with 1024 blocks of 1024 bytes

```
dd if=/dev/zero of=newDisk count=1024 bs=1024
```

To create an ext3 file system

```
/sbin/mkfs.ext3 newDisk
```

To access the file system we need to mount it onto a local directory

```
mkdir mnt
mount -o loop newDisk mnt
```

We may now copy files into the mounted disk image. When complete unmount the directory we used

```
cp myFile mnt
umount mnt
```

8.2.2 Accessing

If we have a diskimage that we have been using and we wish to access files on the disk we can use standard Linux tools.

List the partitions and note the offset of the partition you want to access

```
/sbin/sfdisk -l -uS diskimage
```

Use the offset to calculate an offset in bytes; for example offset of 63 would yield a byte offset of $63 * 512 = 32256$

Make a directory to which the disk can be mounted and mount the disk. You will need to be root to perform the mount operation.

```
mkdir mnt
mount -o loop,offset=32256 diskimage mnt
```

It is now possible to access the partition in the disk image through the mount-point *mnt*.

8.3 Initial RAM Disk

8.3.1 Extract Files from an initrd.gz

This sequence of commands will allow access to the files in an initial ramdisk.

```
gzip -d initrd.gz
mkdir romfs
mount -o loop initrd romfs
```

Move files from romfs to use in a new file system

```
cd romfs
tar cf - .
cd ../<destination>
tar xf -
```

Now the files are available in <destination>. This can be used as the source for creating a new variant of the initial ram disk

8.3.2 Building an initrd.gz

Create a directory into which your files can be written

```
mkdir ramfs
```

copy your files into ramfs (you might want to start by extracting an existing initrd)

```
/sbin/mkfs.cramfs ramfs initrd
gzip initrd
chmod 777 initrd.gz
```

8.3.3 Modifying the boot sequence

The boot sequence is controlled by a single script in `sbin/init`. With the files from the `initrd.gz` file extracted it is simple to edit this file

```
edit ramfs/sbin/init
```

8.3.4 Example Operations When Running from Initial RAM Disk

There is very limited functionality when running from the initial ram disk. However the following are useful operations that can be performed.

8.3.4.1 Make a writeable directory

When booted from an `initrd` image, the root FS is read-only. To make a read/write directory:

```
mount -t tmpfs /dev/ram0 /t2
```

Now `/t2` is a writable directory on the ram disk.

⇒ Any files written here will be lost when simulation is terminated.

8.3.4.2 Configure the NIC

The following commands will enable the Ethernet NIC on the simulated Malta platform.

```
ifconfig lo up
ifconfig eth0 10.0.2.15 up
route add default gw 10.0.2.2
```

We can now access out into the real world ...

Example using `nc` to fetch a page from `google.com`.

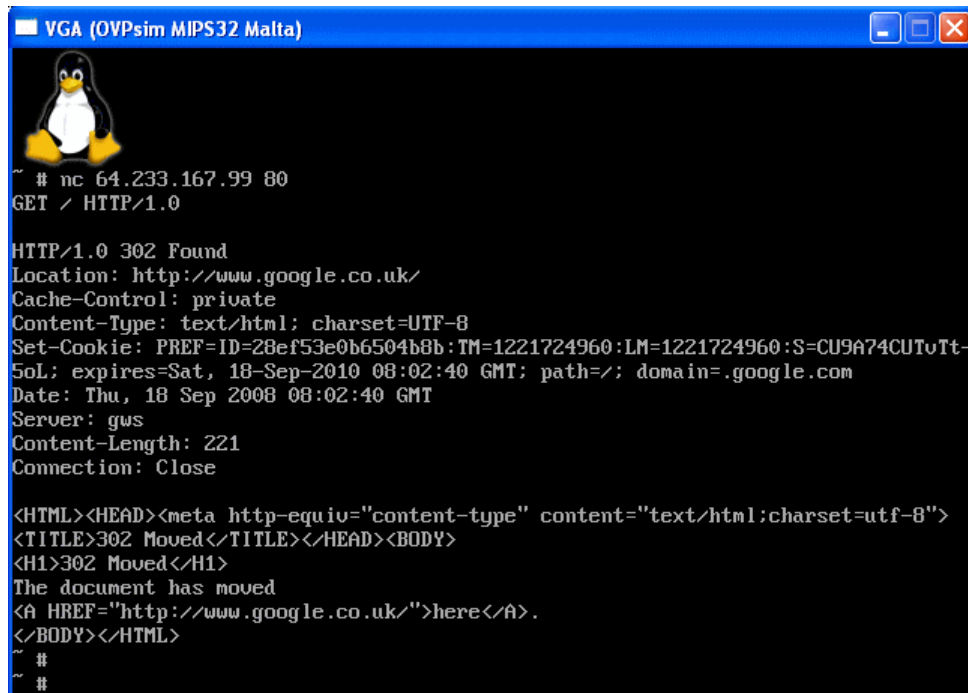

Notes:

1. `nslookup` was used on a Linux machine to get the ip address for `google.com`.
2. There is no further prompt after the `nc` command
3. Two <Carriage Returns> are required after the `GET` command.

In the shell use the nc command and enter the following

```
# nc 64.233.167.99 80
GET / HTTP/1.0
```

The result of this command provides information from the www.google.com website, as shown in the following figure.

```
VGA (OVPsim MIPS32 Malta)
~ # nc 64.233.167.99 80
GET / HTTP/1.0

HTTP/1.0 302 Found

9 Using VNC Server Connection

9.1 *Introduction*

This section provides some example instructions to install and use a VNC server connection to the virtual platform

9.2 *Installation*

.

9.3 *Starting*

10 Re-building the Debian Linux Kernel

10.1 Introduction

This section provides some example instructions to re-build the vmlinux kernel from a Debian distribution. The build is carried out on a Linux platform.

In order to rebuild the Linux kernel it is first necessary to build the Cross-Compiler

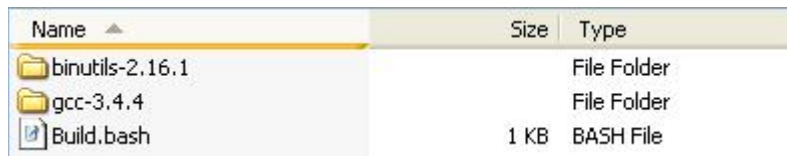

10.2 Building on a Linux Platform

10.2.1 Building the Cross-Compiler

To build a cross-compiler it is first required to obtain **binutils** and **compiler source**. In this example we have used binutils-2.16.1 and gcc-3.4.4. The version of gcc used is dependent upon the support for the target required. The targets we are building are to support MIPS32 Little Endian and MIPS Malta platform.

The information contained in this section is derived from the information available at <http://www.linux-mips.org/wiki/Toolchains#GCC>

In this example we have extracted the binutils and the gcc source into parallel directories, as shown in the following figure

Name	Size	Type
binutils-2.16.1		File Folder
gcc-3.4.4		File Folder
Build.bash	1 KB	BASH File

These are then compiled and installed. We created a script, Build.sh, to store this script.

The build script (Build.sh) for the Cross-Compiler looks like:

```
#!/bin/sh

here=$(pwd)
install=$(dirname $here)/install
mkdir -p ${install}

# First build a linux compiler
export WDIR=/tmp
#export TARGET=mipsel-unknown-linux-gnu
export PREFIX=${install}

export PATH=${PATH}:${PREFIX}/bin

TARGETS="mipsel-unknown-linux-gnu mipsel-malta-linux"
TARGETS=mipsel-malta-linux
for TARGET in $TARGETS; do
```

```
rm -rf b-b
mkdir b-b
pushd b-b
  ../binutils-2.16.1/configure --target=$TARGET --prefix=$PREFIX
  make
  make install
popd

rm -rf b-gcc
mkdir b-gcc
pushd b-gcc
  ../gcc-3.4.4/configure --target=$TARGET --prefix=$PREFIX \
    --enable-languages=c --without-headers \
    --with-gnu-ld --with-gnu-as \
    --disable-shared --disable-threads
  make -j2
  make install
popd
done
```

After execution an install directory is created that includes the directories shown in the following figure:

Name ▲	Size	Type
bin		File Folder
include		File Folder
info		File Folder
lib		File Folder
libexec		File Folder
man		File Folder
mipsel-malta-linux		File Folder
mipsel-unknown-linux-gnu		File Folder
share		File Folder

The bin directory provides tools specific to the mips linux platform.

Name ▲	Size	Type
 mipsel-malta-linux-addr2line	2,406 KB	File

 mipsel-unknown-linux-gnu-strip	2,877 KB	File

10.2.2 Building the Linux Kernel

10.2.2.1 Kernel Build Script

The build script we created for the Linux Kernel looks like:

```
#!/bin/sh

export CROSS_COMPILE_V=/path/to/kernel/install/bin/mipsel-unknown-linux-gnu-
```

```
rm -rf linux-2.6.23.11
tar xvfz linux-2.6.23.11.tar.gz
cp kernel-config linux-2.6.23.11/.config
pushd linux-2.6.23.11
    make CROSS_COMPILE='distcc $(CROSS_COMPILE_V)' CONFIG_DEBUG_INFO=1 -j16
popd
```

10.2.2.2 Kernel Build Configuration

The kernel configuration is contained within the kernel-config file. This defines all the build parameters for the kernel. This was initially created using ‘make config’ for the Linux Kernel and is subsequently stored and copied into the source directory. The actual file used is provided in appendix C.1 MIPS Kernel Configuration File of this document.

10.3 *Building on a Windows Platform*

The building of the Linux Kernel on a Windows platform is not supported.

11 Debugging the Linux Kernel

11.1 *Non-Intrusive Instrumentation*

The Imperas Professional tools provide the VAP (Verification, Analysis and profiling) Tools which provide extensive tools useful for debugging a Linux kernel, including:

- Logging of all exceptions (including TLB)
- Simulation termination on a kernel panic
- Simulation termination on a defined kernel execution event; for example exec of /sbin/halt
- Visibility of kernel execution without console mips32 linux kernel

To find out more about the Imperas Professional tools please contact www.imperas.com.

11.2 *Attaching the Debugger*

See the OVP documents available at www.ovpworld.org to guide the use of a debugger with the MipsMalta platform.

- OVP Debugging Applications with GDB User Guide
- OVP Debugging Applications with Eclipse User Guide

11.2.1 Starting the Platform Simulation

The MipsMalta platform should be started with an additional command line argument to open a port to connect a debugger to.

A batch file provided with the MIPS Malta Platform demonstration should be modified to add "**--port 9998**" that is used to specify an arbitrary port to be opened for connection to a debugger.

The Windows batch file RUN_BootLinux.bat for Windows users is shown modified below

```
...

%PLATFORM_VLN% ^
    --verbose ^
    --ramdisk initrd.gz ^
    --finishonhalt ^
    --kernel vmlinux ^
    --console tty0 ^
    --console tty0 ^
    --override MipsMalta/mipsle1/variant=34Kc ^
    --output imperas.log --port 9998

:end
pause
```

the same modification can be made to the equivalent Linux shell script or to any of the other scripts provided in the demo directory.

The debugger is then attached to this port as described in one of the debugging documents referenced above. The kernel can be thought of as an application running directly on the processor.

12 Transferring Files to Guest Linux

12.1 Introduction

The ability to transfer files compiled on the host system into the Guest, simulated, Linux system is crucial to provide an efficient development environment.

This section provides two methods provided by the MipsMalta platform for transferring files. It assumes you have already set up a full Linux Install as explained in section 7 Installing Full Linux Distribution.

12.2 Using an FTP Server

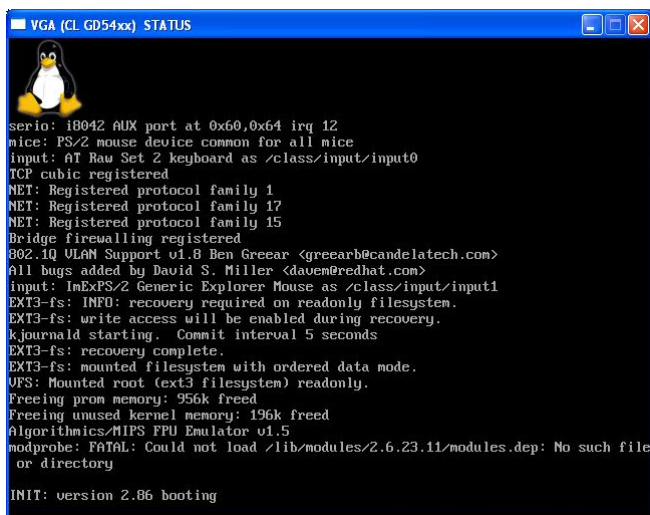

12.2.1 Starting the Simulation

Run the platform, with the script `RUN_BootLinuxVNC` provided in the demo directory **mips_MipsMalta_Linux_install** to pass an additional parameter `--redir` to set redirection of the tcp port 11001 that will be used for the connection between the gdb server and a gdb instance later.

For example, on Windows

```
%PLATFORM_VLNV% ^
--verbose ^
--ramdisk initrd.gz ^
--finishonhalt ^
--kernel vmlinux ^
--console tty0 ^
--output imperas.log ^
--wallclock ^
--redir
```

The supplied disk image performs a full Linux operating system boot.

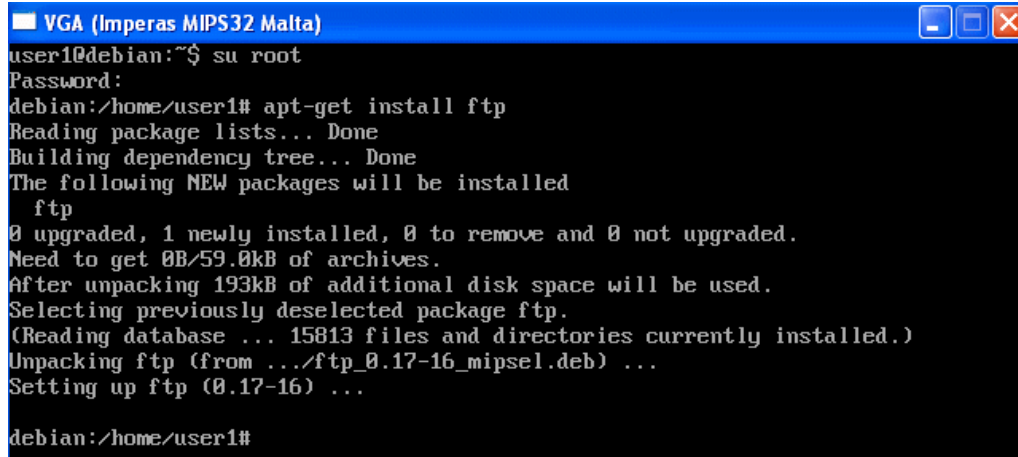

12.2.2 Adding Additional Linux Components

The *ftp* component is required in the Linux operating system to allow the easy transfer of user programs into the simulated Linux environment. This additional component may be installed using *apt-get* and will require root login in the simulated Linux environment.

Login as root and install the *ftp* package.

```
> apt-get install ftp
```

```
VGA (Imperas MIPS32 Malta)
user1@debian:~$ su root
Password:
debian:/home/user1# apt-get install ftp
Reading package lists... Done
Building dependency tree... Done
The following NEW packages will be installed
  ftp
0 upgraded, 1 newly installed, 0 to remove and 0 not upgraded.
Need to get 0B/59.0kB of archives.
After unpacking 193kB of additional disk space will be used.
Selecting previously deselected package ftp.
(Reading database ... 15813 files and directories currently installed.)
Unpacking ftp (from .../ftp_0.17-16_mipsel.deb) ...
Setting up ftp (0.17-16) ...
debian:/home/user1#
```

Now logout as root using the *exit* command.

```
> exit
```

12.2.3 Transfer Files

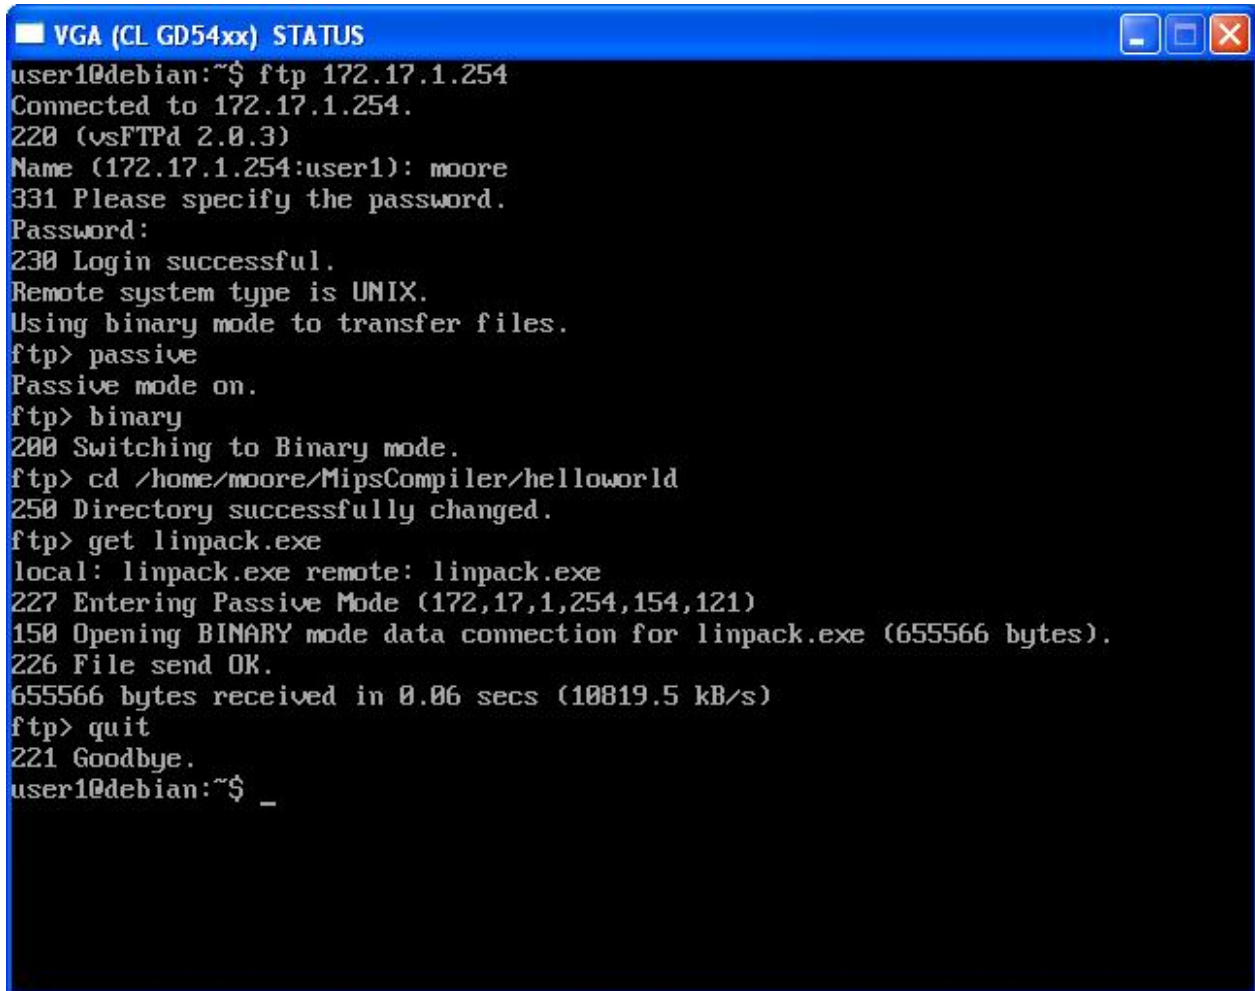

The simulation was executed using the additional command line argument **redir**. This caused a re-direction command of `redir="tcp:15901:10.0.2.15:5901,tcp:11001:10.0.2.15:11001"` to be passed to the NIC peripheral device. This will expose a port that allows a connection to an FTP server.

For this example we have created a version of the *linpack* application by cross-compiling on a linux host system.

login as *user1* (or whatever user account you set up during the installation) and use *ftp* to transfer the compiled program onto the simulated Linux platform from an *ftp* server. For this example we are running an *ftp* server on a host 172.17.1.254

```
% ftp <server>
% login: <login>
% password: <password>
ftp> passive
ftp> cd <directory of executable>
ftp> binary
ftp> get linpack.exe
ftp> quit
```

This is shown in the following screenshot.

```
VGA (CL GD54xx) STATUS
user1@debian:~$ ftp 172.17.1.254
Connected to 172.17.1.254.
220 (vsFTPd 2.0.3)
Name (172.17.1.254:user1): moore
331 Please specify the password.
Password:
230 Login successful.
Remote system type is UNIX.
Using binary mode to transfer files.
ftp> passive
Passive mode on.
ftp> binary
200 Switching to Binary mode.
ftp> cd /home/moore/MipsCompiler/helloworld
250 Directory successfully changed.
ftp> get linpack.exe
local: linpack.exe remote: linpack.exe
227 Entering Passive Mode (172,17,1,254,154,121)
150 Opening BINARY mode data connection for linpack.exe (655566 bytes).
226 File send OK.
655566 bytes received in 0.06 secs (10819.5 kB/s)
ftp> quit
221 Goodbye.
user1@debian:~$ _
```

Check the permissions on the transferred file to ensure that it is executable from a user login. If it cannot be executed you can use the `chmod` command, for example

```
chmod +x linpack.exe
```

12.3 Using TFTP

If no FTP server is available or all the files to be transferred are available on the local Host machine it is possible to use the simpler TFTP protocol.

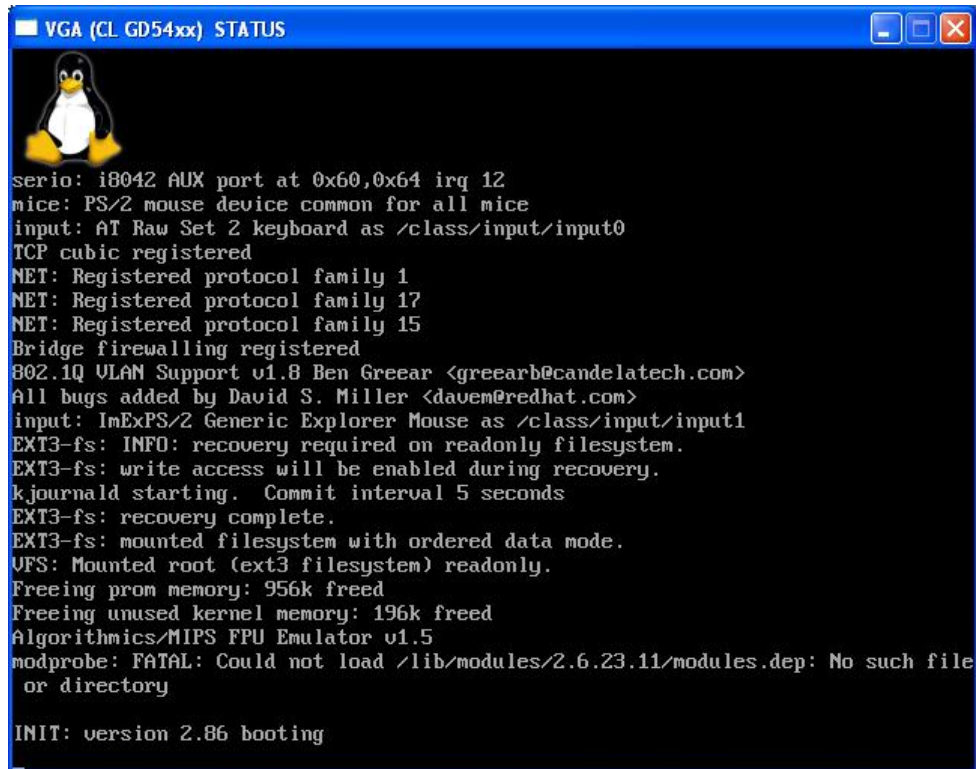

The NIC peripheral includes an emulated TFTP server that intercepts all TFTP packets being sent from the guest operating system. Only the command *get* is supported to load files from the Host into the guest operating system. The TFTP requests for files are translated to file operations on the Host machine. The files must be transferred in *binary* mode.

12.3.1 Starting the Simulation

Run the platform, modifying the script file `RUN_BootLinux` provided in the **Demo_Linux_MipsMalta_install** installation to pass an additional parameter `--tftp <path>` to enable the emulated TFTP server and set the root directory on the Host machine, as shown below for Linux

```
PLATFORM_VLNV \  
    --verbose \  
    --ramdisk initrd.gz \  
    --finishonhalt \  
    --kernel vmlinux \  
    --console tty0 ^  
    --output imperas.log \  
    --wallclock \  
    --tftp <path>
```

The supplied disk image performs a full Linux operating system boot.

```
VGA (CL GD54xx) STATUS  
serio: i8042 AUX port at 0x60,0x64 irq 12

modprobe: FATAL: Could not load /lib/modules/2.6.23.11/modules.dep: No such file  
or directory  
INIT: version 2.86 booting
```

12.3.2 Adding Additional Linux Components

The tftp component may need to be added to the Linux installation. This component will be installed using apt-get and will require root login in the simulated Linux environment.

Login as root and install the TFTP package using the command

```
> apt-get install tftp
```

```
user1@debian:~$ su root
Password:
debian:/home/user1# apt-get install tftp
Reading package lists... Done
Building dependency tree... Done
The following NEW packages will be installed
  tftp
0 upgraded, 1 newly installed, 0 to remove and 0 not upgraded.
Need to get 0B/19.5kB of archives.
After unpacking 98.3kB of additional disk space will be used.
Selecting previously deselected package tftp.
(Reading database ... 15815 files and directories currently installed.)
Unpacking tftp (from .../tftp_0.17-15_mipsel.deb) ...
Setting up tftp (0.17-15) ...
debian:/home/user1# _
```

now logout as root using the *exit* command.

```
> exit
```

12.3.3 Transfer Files into Guest Operating System

The simulation was executed with the additional command line argument **tftp <tftpPrefix>**. This enabled the emulation of the TFTP server within the NIC peripheral. The root from which files are transferred is defined by the path addition to the tftp argument. The argument to the *get* command must be an absolute path, though it is converted to a path relative to the *tftpPrefix* argument to the model. For example, if we have a file *C:\workspace\userApp\myFile.exe*; we can specify the command line argument as *tftp C:\workspace* and access the file in tftp using the command *get /userApp/myFile.exe*.

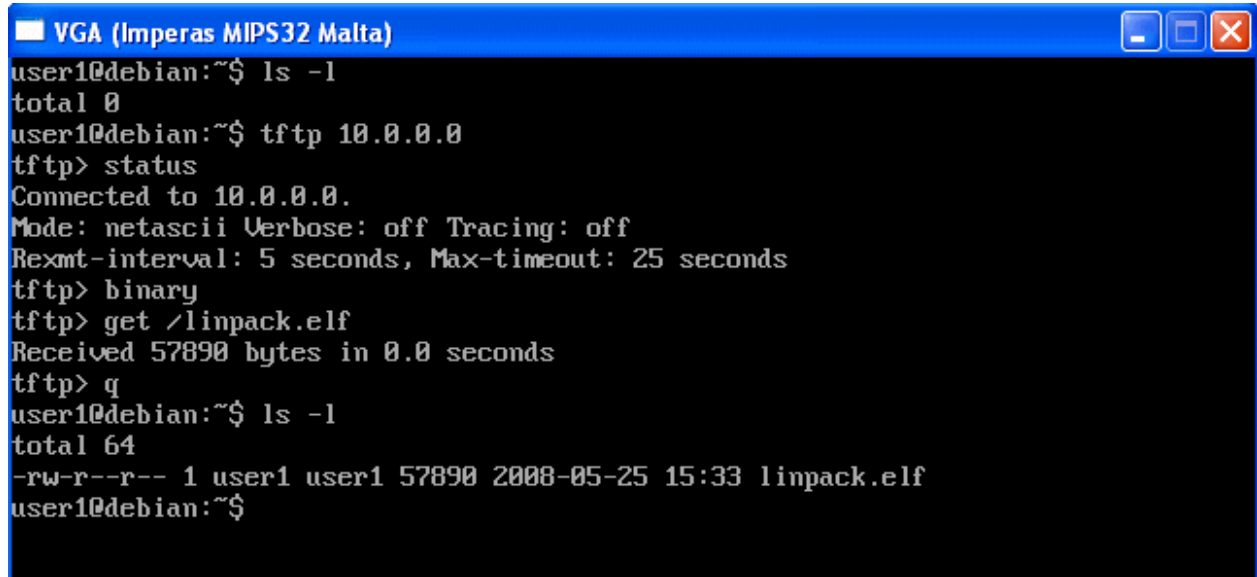

For the following example we have created a version of the linpack application by cross-compiling on a linux host system using the MIPS Linux cross compiler. This is contained in a directory userApp that resides within the directory to which we have set the root using the tftp argument.

login as user1 (or whatever user account you set up during the installation) and use tftp to transfer the compiled program onto the simulated Linux platform.

```
% tftp <host>
tftp> binary
tftp> get /userApp/linpack.exe
tftp> quit
```

⇒ <host> should be set to any IP address that is NOT the local host ip address.

This is shown in the following screenshot.

```
VGA (Imperas MIPS32 Malta)
user1@debian:~$ ls -l
total 0
user1@debian:~$ tftp 10.0.0.0
tftp> status
Connected to 10.0.0.0.
Mode: netascii Verbose: off Tracing: off
Rexmt-interval: 5 seconds, Max-timeout: 25 seconds
tftp> binary
tftp> get /linpack.elf
Received 57890 bytes in 0.0 seconds
tftp> q
user1@debian:~$ ls -l
total 64
-rw-r--r-- 1 user1 user1 57890 2008-05-25 15:33 linpack.elf
user1@debian:~$
```

Check the permissions on the transferred file to ensure that it is executable from a user login. If it cannot be executed you can use the `chmod` command, for example

```
chmod +x linpack.exe
```

13 Debugging Linux User Applications

13.1 Introduction

Once the Linux kernel is up and running it is the user applications themselves that need to be debugged.

In the OVPsim environment it is simple to connect a debugger, such as command line GDB or a GUI like DDD or Eclipse, to a user application running on the simulated Linux operating system. This is accomplished using one or more instances of gdbserver running in the simulated Linux environment.

This section describes additional components that may be required in the simulated Linux environment and the steps required to accomplish user application debugging.

13.2 Linux Installation

There must be a standard Linux installation available on a disk image. Section 7 describes how to build a full Linux installation disk.

13.3 Booting Linux

Run the platform from the command line or by executing a modified version of the batch file bootLinux.bat provided.

This will execute the platform provided, passing in the Linux kernel as the first parameter.

Additional arguments may be used to enable file transfer by FTP or TFTP.

13.3.1 Redirecting TCP Port

Add the '--redir' argument to set redirection of the tcp port 11001. This will enable both the connection between the gdb server and a gdb instance later and transferring files, see section 12.2 Using an FTP Server for more details.

```
PLATFORM_VLNV \  
  --verbose \  
  --ramdisk initrd.gz \  
  --finishonhalt \  
  --kernel vmlinux \  
  --console tty0 ^  
  --output imperas.log \  
  --wallclock \  
  --redir
```

13.3.2 Enabling TFTP File Transfer

Add the TFTP <path> argument to enable TFTP with the root server directory, on the host, set to <path>. See section 12.3 Using TFTP for more details

```
PLATFORM_VLNV ^
    --verbose ^
    --ramdisk initrd.gz ^
    --finishonhalt ^
    --kernel vmlinux ^
    --console tty0 ^
    --output imperas.log ^
    --wallclock ^
    --tftp "C:\workspace"
```

13.4 Compiling a User Program

13.4.1 Cross Compiler ToolChain

The toolchain used to compile the user application is the MIPS GNU/Linux toolchain available from the CodeSourcery website at

<http://www.codesourcery.com/sgpp/lite/mips/portal/subscription?@template=lite>

There are installers for Linux and Windows (MINGW) host platforms.

The version of installer used by Imperas for the generation of this example was 4.2-129

13.4.2 Cross Compiler Make Environment

The toolchain is extracted into a directory mips-4.2, we add this onto our path

```
export PATH=${PATH}:/path/to/installation/mips-4.2/bin
```

We can then use a Makefile to build our user application. The following Makefile uses the cross compiler to generate an exe file from a source c file, led_flash.c. It also generates the symbol table and an assembler listing (objdump) for use in debug.

```
CFLAGS = -EL -msoft-float -static -g
LDFLAGS= -lm
CC = mips-linux-gnu-gcc $(CFLAGS)
NM = mips-linux-gnu-nm -n
OD = mips-linux-gnu-objdump -D

ALL = led_flash.exe

all: $(ALL)

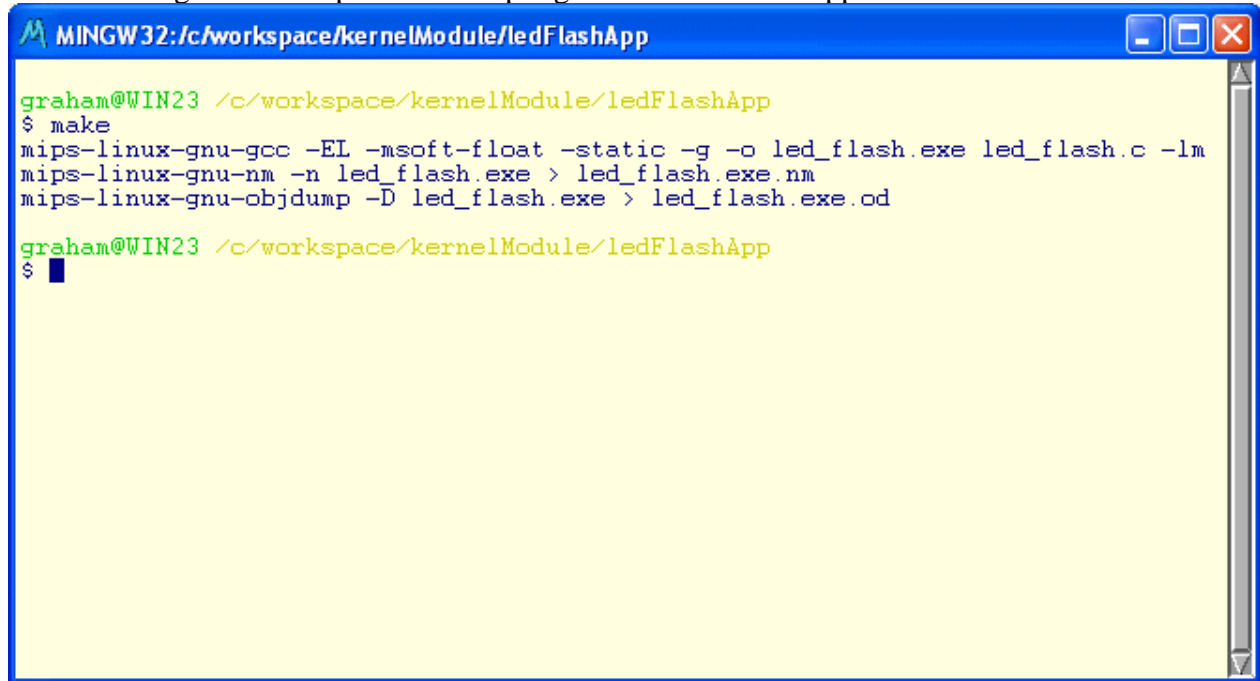

%.exe: %.c
    $(CC) -o $@ $(<) $(LDFLAGS)
    $(NM) $@ > $(@).nm
    $(OD) $@ > $(@).od
```

```
clean:
    rm -f $(ALL)
    rm -f $(ALL).nm
    rm -f $(ALL).od
```

13.4.3 Building the Application

We can now simply build the application into an executable ready to be loaded onto the MipsMalta platform and executed by typing make at the command line.

The following is an example of the output generated when the application is built.

A screenshot of a MINGW32 terminal window titled "MINGW32:/c/workspace/kernelModule/ledFlashApp". The window has a blue title bar and standard Windows window controls. The terminal output shows the execution of the 'make' command, which runs three compilation steps: 1. 'mips-linux-gnu-gcc -EL -msoft-float -static -g -o led_flash.exe led_flash.c -lm', 2. 'mips-linux-gnu-nm -n led_flash.exe > led_flash.exe.nm', and 3. 'mips-linux-gnu-objdump -D led_flash.exe > led_flash.exe.od'. The prompt then returns to the user, showing 'graham@WIN23 /c/workspace/kernelModule/ledFlashApp' and '\$' with a cursor.

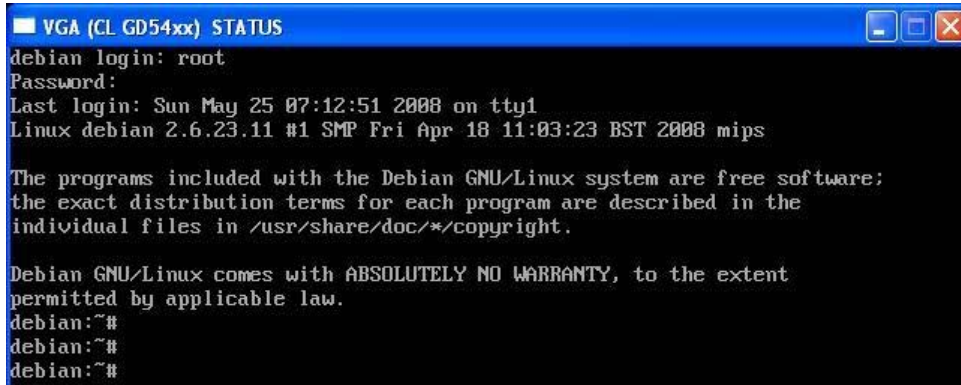

```
MINGW32:/c/workspace/kernelModule/ledFlashApp
graham@WIN23 /c/workspace/kernelModule/ledFlashApp
$ make
mips-linux-gnu-gcc -EL -msoft-float -static -g -o led_flash.exe led_flash.c -lm
mips-linux-gnu-nm -n led_flash.exe > led_flash.exe.nm
mips-linux-gnu-objdump -D led_flash.exe > led_flash.exe.od
graham@WIN23 /c/workspace/kernelModule/ledFlashApp
$
```

This application can now be transferred into the MIPS Malta Linux simulation and executed. See the following section that takes you through this process.

13.5 Adding Additional Linux Components

The *gdb* component is required in the Linux operating system to enable debugging of the user application. This includes *gdb server* to allow the connection of a debugger running on the native host. This component will be installed using *apt-get* and will require root login in the simulated Linux environment.

Login as root

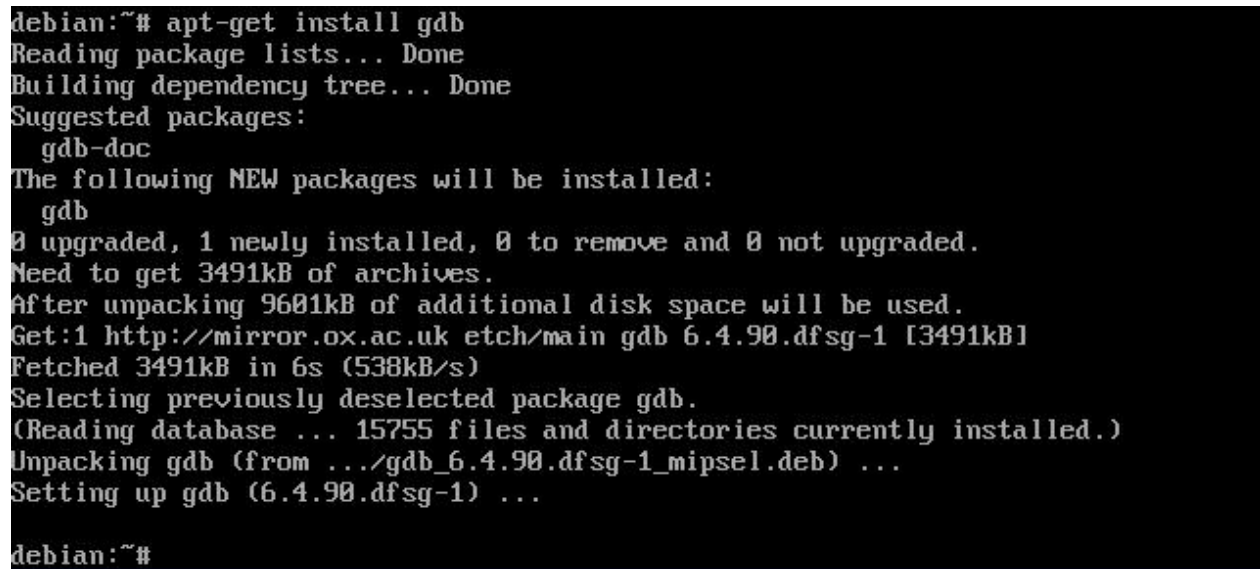

```
VGA (CL GD54xx) STATUS
debian login: root
Password:
Last login: Sun May 25 07:12:51 2008 on tty1
Linux debian 2.6.23.11 #1 SMP Fri Apr 18 11:03:23 BST 2008 mips

The programs included with the Debian GNU/Linux system are free software;
the exact distribution terms for each program are described in the
individual files in /usr/share/doc/*/copyright.

Setting up gdb (6.4.90.dfsg-1) ...

debian:~#
```

now logout as root using the *exit* command.

13.6 Remote Debug using GDBserver

13.6.1 Starting GDB Server

Run the program, under gdbserver, using the port on the localhost that has been mapped onto the host machine port of the same number.

```
% gdbserver localhost:11001 ./linpack.exe
```

```
user1@debian:~$ gdbserver localhost:11001 ./linpack.exe &  
[1] 2281  
user1@debian:~$ Process ./linpack.exe created; pid = 2282  
Listening on port 11001  
_
```

13.6.2 Connecting to GDB Server

13.6.2.1 Using Eclipse

TBA

13.6.2.2 Using DDD from a Linux Host

In this example we are using a version of mips gdb, built for a Linux host, to connect to the gdbserver running in the OVPsim simulated Linux environment, on a Windows based PC.

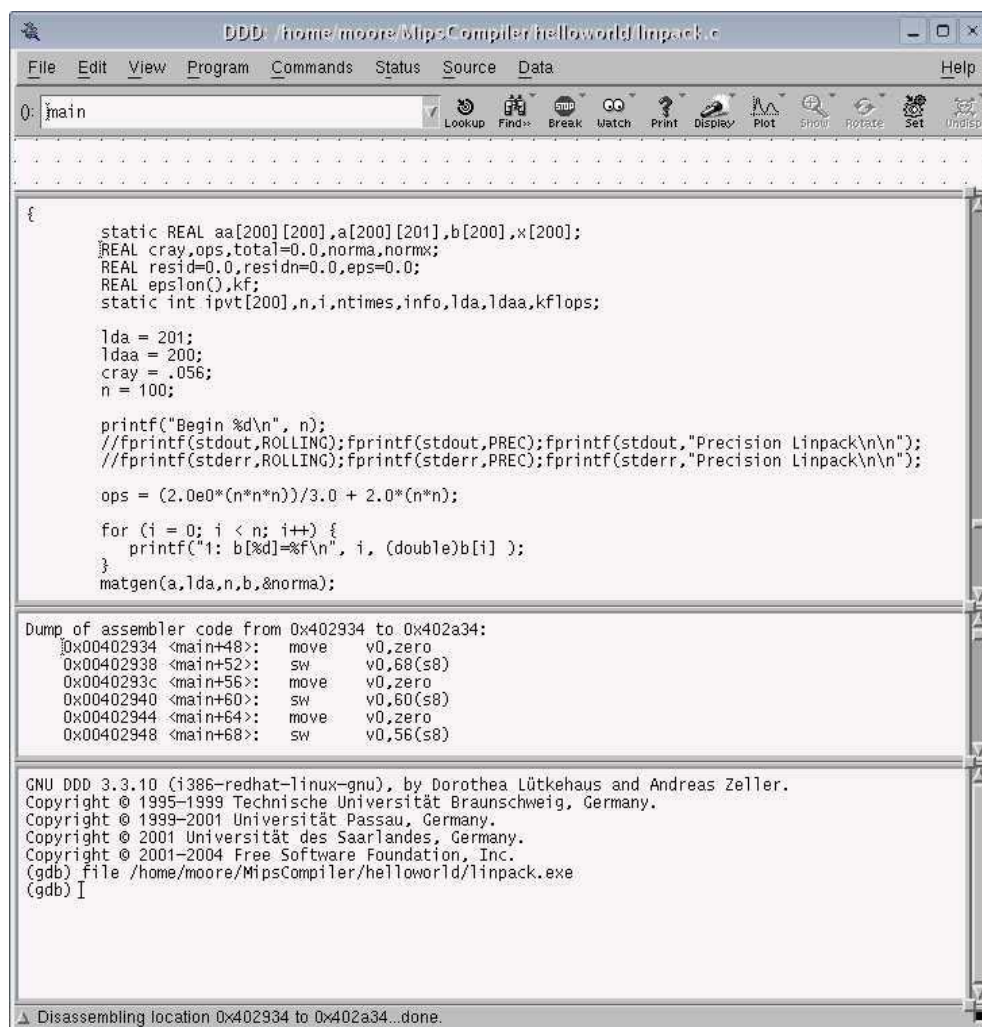

On any Linux machine start a debug session using command line gdb or gui ddd (must specify the specific gdb version to use so that it is compatible with the gdb server installation in the simulated Linux environment).

```
% ddd --debugger gdb6.4/install/bin/mipsel-linux-gnu-gdb
```

This will start the DDD GUI.

In the command prompt the file to be debugged should be loaded using the command

```
(gdb) file linpack.exe
```

We should now be able to connect to the port on the Windows host on which the simulation is running

```
(gdb) target remote win23:11001
```

13.6.2.3 Using GDB from local Windows Host

In this example we are using a version of `mips gdb`, built for a Windows host, to connect to the `gdbserver` running in the OVPsim simulated Linux environment, on a Windows based PC.

On the local Windows machine start a debug session using command line `gdb`.

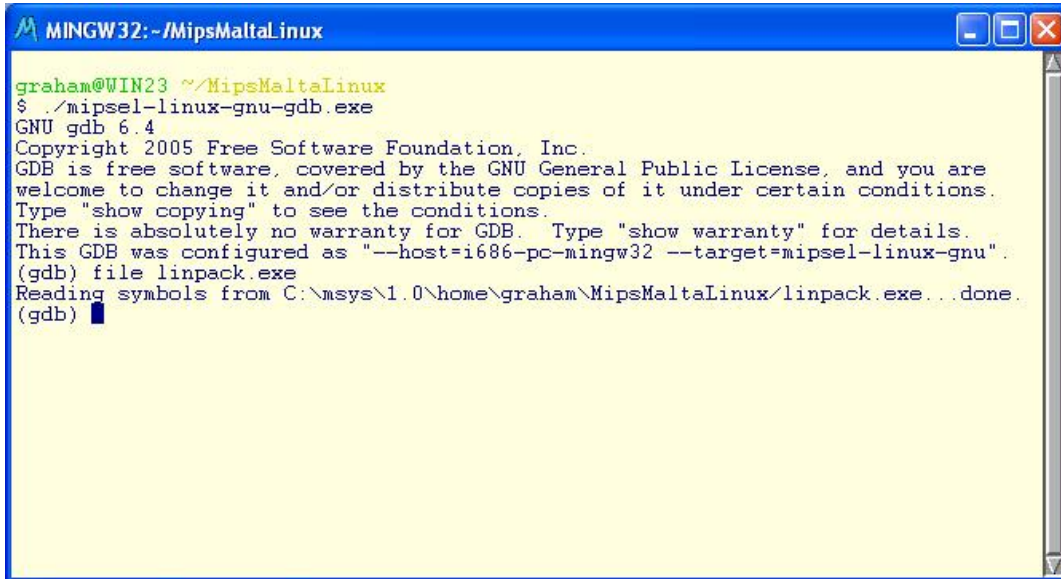

```
% ./mipsel-linux-gnu-gdb
```

This will start the GDB command line debugger.

In the command prompt the file to be debugged should be loaded using the command

```
(gdb) file linpack.exe
```

We should now be able to connect to the port on the Windows host on which the simulation is running

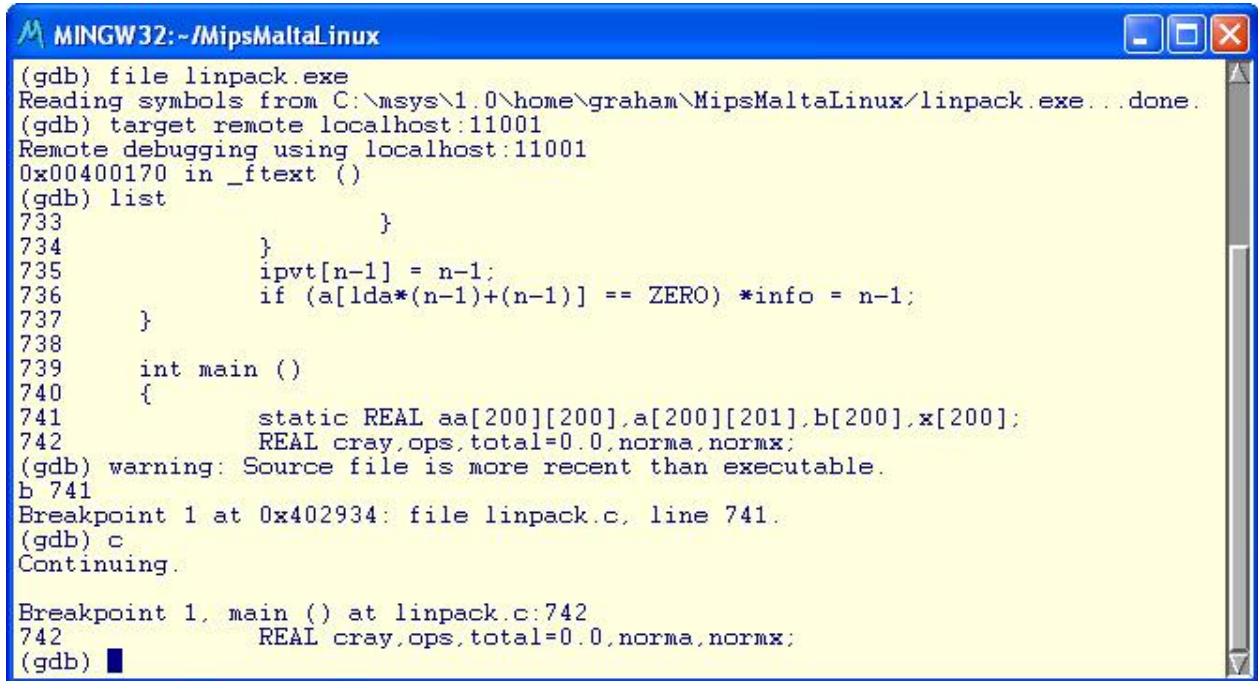

```
MINGW32: ~/MipsMaltaLinux
graham@WIN23 ~/MipsMaltaLinux
$ ./mipsel-linux-gnu-gdb.exe
GNU gdb 6.4

```

13.6.3 Debugging Multiple Applications in Parallel

Each application instance to be debugged will require:

1. a port to be exported from the simulation,
2. a gdb server instance in the simulated Linux environment
3. a ddd/gdb debugging instance on a Host machine

In order to export additional ports the platform.c file will need to be modified to change the parameter passed to the Ethernet NIC peripheral. This is passed using the op function in the platform, as shown below

```

opParamStringOverride(mi, NIC "redir",
"tcp:15901:10.0.2.15:5901,tcp:11001:10.0.2.15:11001");
  
```

To add additional ports the string is constructed as provided in the following example that exports two ports.

```

opParamStringOverride(mi, NIC "redir",
"tcp:15901:10.0.2.15:5901,tcp:11001:10.0.2.15:11001,tcp:11002:10.0.2.15:11002");
  
```

13.7 Debug using Simulated GDB

Debugging can also be carried out using a GDB session running within the simulated Guest Linux.

In this case the source code should also be transferred onto the simulated platform using the FTP or TFTP methods described earlier. Start GDB using the command

```
> gdb linpack.exe
```

```
debian:/home/user1# ls -l
total 672
-rw-r--r-- 1 root root 22340 2008-05-25 17:46 linpack.c
-rwxr-xr-x 1 root root 655574 2008-05-25 17:47 linpack.exe
debian:/home/user1# gdb linpack.exe
GNU gdb 6.4.90-debian

14 Creating an Example Linux Kernel Module

14.1 Introduction

This section provides some information to help with the creation of new kernel driver modules and how these can be developed on the simulated platform.

The example in this section is a character device driver for the 8 character LED that is defined as part of the Malta FPGA device.

14.2 Pre-Requisites

There are pre-requisites to being able to build a driver kernel module, namely

- source of the linux kernel
- cross compiler for building the linux kernel

These were previously discussed in the section 10.2.1 “Building the Cross-Compiler” and section 10.2.2 “Building the Linux Kernel”. Please see these sections for instructions if they have not already been performed.

14.3 Starting the Platform Simulation

The MipsMalta platform should be started with additional command line arguments, as used previously, to export a TCP port (redir) and tftp root (tftp) to allow easy transfer of files into the Guest Operating System and run in real time (wallclock).

Using one of the example script files it should be modified as shown below (for Windows)

```
%PLATFORM_VLVN% ^
--verbose ^
--ramdisk initrd.gz ^
--finishonhalt ^
--kernel vmlinux ^
--console tty0 ^
--output imperas.log ^
--wallclock ^
--redir ^
--tftp "C:\workspace\kernelModule"
```

14.4 Example Source

This section contains example code for a simple device driver. The device driver allows the LED register in the Malta FPGA to be accessed for reading and writing.

14.4.1 Included Header Files

The header files that are used in the Kernel device driver

```
#include <linux/kernel.h>
#include <linux/module.h>
#include <linux/init.h>
#include <linux/fs.h>          /* character device definitions    */
```

This next header file is used to define the register in the MIPS Malta FPGA that is used to access the LEDs.

```
#include "MipsMalta.h"
```

14.4.2 Callback Table and Functions

14.4.2.1 Table

A table provides the list of functions provided by this device driver.

```
struct file_operations ops =
{
    .owner      = THIS_MODULE,
    .open       = led_open,
    .release    = led_release,
    .read       = led_read,
    .write      = led_write
};
```

14.4.2.2 Device Open

```
/*
 * called whenever a process attempts to open the device
 */
static int led_open (struct inode *inode, struct file *file)
{
    printk ("led_open: %d.%d\n", MAJOR(inode->i_rdev), MINOR(inode->i_rdev));
    return 0 ;
}
```

14.4.2.3 Device Close

```
/*
 * Called when a process closes the device.
 */
static int led_release (struct inode *inode, struct file *file)
{
    printk ("led_release\n");
    return 0;
}
```

14.4.2.4 Device Read

```
/*
 * read entry point:
 */
static ssize_t led_read (struct file *file,
                        char *buffer,      /* The buffer to fill with data */
                        size_t length,     /* The length of the buffer */
                        loff_t * offset)   /* Our offset in the file */
{
    unsigned char c;

    /* Read from physical LED register */
    c = *(char *)LED_REG;

    printk ("led_read: %x\n", (unsigned int)c);

    if (put_user (c, buffer) != 0)
        return -EFAULT;

    return 1;          /* read() always returns exactly one byte */
}
```

14.4.2.5 Device Write

```
/*
 * write entry point:
 */
static ssize_t led_write (struct file *file,
                        const char *buffer, /* buffer */
                        size_t length,     /* length of buffer */
                        loff_t * offset)   /* offset in the file */
{
    unsigned char c;

    if (get_user (c, buffer) != 0)
        return -EFAULT;

    printk ("led_write: %x\n", (unsigned int)c);

    /* Write to physical LED register */
    *(char *)LED_REG = c;

    return 1;
}
```

14.4.3 Device Module Initialize and Exit

14.4.3.1 Device Initialization

This is the function invoked when the kernel module is installed.

```
/*
 * Initialize the driver - Register the character device
 */
static int led_init (void)
{
    int ret;

    printk ("LED driver: hello\n") ;
    ret = register_chrdev (LED_MAJOR, DEVICE_NAME, &ops);
    if (ret != 0)
        return ret;
    return 0;
}
```

14.4.3.2 Device Exit

This is the function invoked when the kernel module is removed.

```
void led_exit (void)
{
    printk ("LED driver: goodbye\n");
    unregister_chrdev (LED_MAJOR, DEVICE_NAME);
}
```

14.4.3.3 Register Module

Define module functions used for initialization and exiting

```
module_init (led_init);
module_exit (led_exit);
```

14.5 *Building the Device Driver*

14.5.1 Makefiles

For convenience we are using two Makefiles. The first Makefile sits in the directory containing the driver source code and sets the object module to the driver name object.

```
obj-m := led_drv.o
```

The second is common to all kernel modules and specifies the module to be compiled, using `M='mymoduledirectory'`

```
COMPILER=/path/to/compiler/install
CROSS_COMPILE_V=${COMPILER}/bin/mipsel-malta-linux-
KERNELSRC=/path/to/source/linux-2.6.23.11
MYMODULE=$(shell pwd)/ledDrvModule

default:
    make CROSS_COMPILE=${CROSS_COMPILE_V} -C ${KERNELSRC} M=${MYMODULE} modules
```

Of course these can be combined into a single Makefile that would reside in the directory with the source files

```
COMPILER=/path/to/compiler/install
CROSS_COMPILE_V=${COMPILER}/bin/mipsel-malta-linux-
KERNELSRC=/path/to/source/linux-2.6.23.11

obj-m += led_drv.o

default:
    make CROSS_COMPILE=${CROSS_COMPILE_V} -C ${KERNELSRC} modules SUBDIRS=$(PWD)
```

14.5.2 Building

The tools available allow the driver to be built on a Linux host machine, in the same way that the Linux kernel is re-built only on a Linux host.

Building the example kernel module using the Makefile, shown above, will provide output similar to that below:

```

[graham@lnx16: ~/playground/kernelModule/ledDriver]$ make
make CROSS_COMPILE=/home/nda/mips/linux/install/bin/mipsel-malta-linux- -C /home/graham/workspaceMalta/mipsKernel/linux-2.6.23.11
M=/home/graham/playground/kernelModule/ledDriver/ledDrvModule modules
make[1]: Entering directory `/home/graham/workspaceMalta/mipsKernel/linux-2.6.23.11'
CC [M] /home/graham/playground/kernelModule/ledDriver/ledDrvModule/led_drv.o
Building modules, stage 2.
MODPOST 1 modules
CC /home/graham/playground/kernelModule/ledDriver/ledDrvModule/led_drv.mod.o
LD [M] /home/graham/playground/kernelModule/ledDriver/ledDrvModule/led_drv.ko
make[1]: Leaving directory `/home/graham/workspaceMalta/mipsKernel/linux-2.6.23.11'
[graham@lnx16: ~/playground/kernelModule/ledDriver]$

```

14.6 Installing the Kernel Module

The file created is a .ko file and this should be transferred into the MIPS Malta Linux platform in the same way as a user application is transferred, as described in section 12 “Transferring Files to Guest Linux”.

The kernel module can only be installed from the root account.

First we use **mknod** to make a directory entry and corresponding i-node for a special file.

```
mknod /dev/led c 42 0
```

We provide the name of the device as /dev/led, c defines the device as a character device, the major device number 42 that helps the operating system find the device driver code and the minor device number 0 used to select the line number. The Major number 42 is reserved for examples and demos.

⇒ the Major number used when the entry is created corresponds to the value used in the driver source code during the initialization, as the argument to the function `register_chrdev()`, see 14.4.3.1 “Device Initialization”

There will now be an entry in /dev called led.

We must make this file writable for all accounts

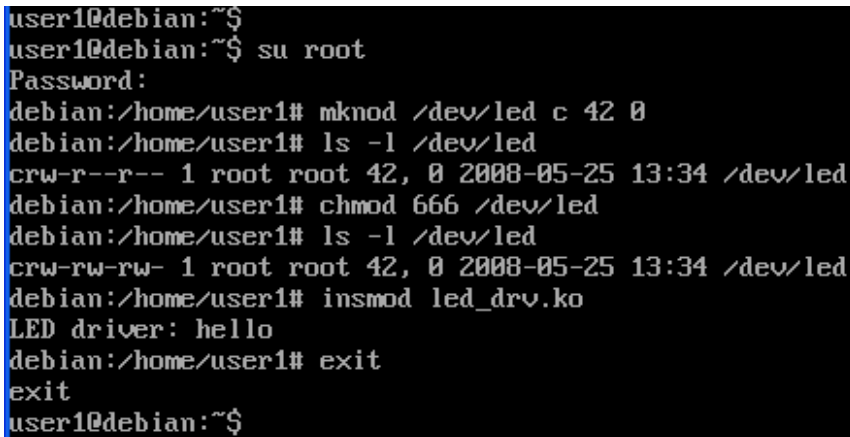

```
chmod 666 /dev/led
```

We now use **insmod** to install our device driver

```
insmod led_drv.ko
```

When installed the driver initialization function is executed.

The following screenshot shows the installation of the led_driver on the MIPS Malta Linux platform simulation.

```
user1@debian:~$  
user1@debian:~$ su root  
Password:  
debian:/home/user1# mknod /dev/led c 42 0  
debian:/home/user1# ls -l /dev/led  
crw-r--r-- 1 root root 42, 0 2008-05-25 13:34 /dev/led  
debian:/home/user1# chmod 666 /dev/led  
debian:/home/user1# ls -l /dev/led  
crw-rw-rw- 1 root root 42, 0 2008-05-25 13:34 /dev/led  
debian:/home/user1# insmod led_drv.ko  
LED driver: hello  
debian:/home/user1# exit  
exit  
user1@debian:~$
```

14.7 Kernel Module Test Application

A simple test application is created to test the operation of the driver. This will open the file that was created with mknod to gain access to the device.

```
const char *deviceName = "/dev/led";  
  
if ((fh = open (deviceName, O_WRONLY)) < 0) {  
    char error[64] = {"open "};  
    strncat(error, deviceName, strlen(deviceName));  
    perror (error);  
    return 0;  
}
```

It will then write characters to the device. This is a sequence comprising a walking '1' interspersed with a write of zero. usleep is used to create a delay between each write.

```
int repeat=25;  
while (repeat--)  
{  
    c = 0;  
    write (fh, &c, 1);  
    usleep (500000);  
    c = 1 << (repeat %8);  
    write (fh, &c, 1);  
    usleep (500000);  
}
```

When complete the device is closed

```
close (fh);
```

This is built using the same Makefile and Cross Compiler toolchain as described in section 13.4 “Compiling a User Program”.

The .exe file created should be transferred into the MIPS Malta Linux platform in the same way as a user application is transferred, as described in section 12 “Transferring Files to Guest Linux”.

We can now test our application and driver in conjunction with the peripheral device.

When running the application, it first opens the device and then writes characters. The device driver has been written including with debug printf statements which are seen in the console.

```
user1@debian:~$  
user1@debian:~$ ./led_flash.exe  
led_open: 42.0  
led_write  
led_write: 0  
led_write: done  
led_write  
led_write: 1  
led_write: done  
led_write  
led_write: 0  
led_write: done  
led_write  
led_write: 80  
led_write: done
```

When complete the device is closed.

```
led_write: 2  
led_write: done  
led_write  
led_write: 0  
led_write: done  
led_write  
led_write: 1  
led_write: done  
led_release  
user1@debian:~$
```

15 Debugging a Statically Linked Linux Kernel Module

As the kernel module is statically linked into the kernel all symbolic information for the kernel module will be available.

This allows the module to be debugged in the same way as a kernel can be debugged, see section 11 "Debugging the Linux Kernel"

16 Debugging a Dynamically loaded Linux Kernel Module

It is difficult to debug a Linux Kernel Module (LKM) especially when it is dynamically loaded from a compiled relocatable object because it resides in virtual memory. This means there are no symbols and no information about where the module resides in memory.

However, the Imperas Multiprocessor Debugger provides functionality to allow source level debug of LKMs without any changes to the original Linux kernel.

16.1 Pre-Requisites

You will need to have obtained and installed a version of the Imperas tools and the demo installers.

These can be made available from the user area on www.imperas.com by contacting Imperas at info@imperas.com.

Two demonstrations are provided by Imperas, for registered Imperas users, to show both the capabilities to debug a Linux kernel, including a dynamically loaded kernel module (LKM) and the use of the Imperas Verification, Analysis and Profiling (VAP) tools; these are Imperas_idebug_linux_MipsMalta and Imperas_ivap_linux_MipsMalta respectively.

These demo installers include a version of the MIPS Malta Linux Kernel with symbolic information.

16.2 Starting the Platform Simulation

The Imperas simulator is invoked using *Imperas.exe*. the platform may be loaded from the VLNV library or by loading the platform shared object or Dynamic Link Library.

⇒ In the following please update the path to the working directory if using the TFTP method for transferring files into the guest operating system.

16.2.1 Invoking with VLNV Library

Within the VLNV library is a description of the standard MipsMalta platform. This can be selected by the Imperas harness and overrides applied to make configuration changes to the platform.

The invocation of Imperas with the MipsMalta platform is shown below

```
harness.exe --verbose ^
--modulename MipsMalta --modulevender "mips.ovpworld.org" ^
--objfile vmlinux --reset 0xbfc00000 ^
--output imperas.log ^
--approxtimer --wallclockFactor 3 ^
--override MipsMalta/Core_Board_SDRAM_promInit/initrd=initrd.gz ^
```

```
--override MipsMalta/mipsle1/variant=24KEc ^  
^  
--enabletools ^  
--extlib MipsMalta/mipsle1=linuxOsHelper ^  
^  
--idebug ^
```

This basic invocation is provided in the Imperas_idebug_linux_MipsMalta demo directory in the script DEBUG_lkm_linux_mipsmalta. This will run scripts to guide you through the LKM debug, if you wish to manually enter the commands remove the line

to remove the replay of commands in the simulated linux

```
--override MipsMalta/Ps2Control/replay=Ps2ControlInput.rec
```

to remove the debug commands

```
--batch lkm_debug_linux_mipsmalta.tcl
```

The following additions / changes are made in order to provide the same features that were enabled previously

Change the boot method to boot from disk image

```
--override MipsMalta/Core_Board_SDRAM_promInit/initrd=initrd.gz ^
```

becomes

```
--override MipsMalta/Core_Board_SDRAM_promInit/root="/dev/hda1" ^
```

And add drive, redirection and directory information

```
--override MipsMalta/PIIX4-IDE/Drive0Name="mipsel_hda" ^  
--override  
MipsMalta/PCI_NET/redir="tcp:15901:10.0.2.15:15901,tcp:11001:10.0.2.15:11001" ^  
--override MipsMalta/PCI_NET/tftpPrefix="<path\to\driver\working\directory>"
```

16.2.2 Invoking from Platform Executable

The C platform executable can be executed directly.

```
$IMPERAS_VLNV/lib/$IMPERAS_ARCH/ImperasLib/mips.ovpworld.org/platform/MipsMalta/1.0/pla  
tform.$IMPERAS_ARCH.exe --verbose \  
    --kernel vmlinux --wallclock \  
    --tftp "C:\workspace" \  
    --output imperas.log \  
    --approxtimer \  
    \  
    --enabletools \  
    --extlib MipsMalta/mipsle1/os=linuxOsHelper \  
    ^  
    --mpdconsole ^
```

16.2.3 Debug Startup

The debugger will load the platform and then wait at the debug prompt for input

```

idebug (mips1e1) >
```

At the initial prompt type continue (or c) to start the simulation. After the Linux operating system has booted we return control to the debugger by interrupting with control-C.

16.3 Registering Kernel Module with Debugger

The development provides a command, *debugKernelModule*, which allows the name of a kernel module that will be loaded sometime in the future to be registered with the debugger. When the kernel module is loaded, using the *insmod* command, a breakpoint will be set at the start of the function defined with *module_init*.

The kernel module is loaded at an arbitrary kernel address and fixed up for execution by the kernel during the loading process. This requires that the kernel is built to be relocatable and as such there is no symbol table available for the loaded kernel module.

When the debugger hits the breakpoint created on the code executed by the *insmod* command, the debugger introspects the kernel to discover the module load address and creates a symbol table.

⇒ The .ko and .c file of the kernel module must be available in the directory from which the simulation was started

This allows symbolic debug of the loaded kernel module; for example adding breakpoints onto the other functions within the kernel driver module by name.

16.4 Debugging the Kernel Module

This section assumes we are using the same kernel module that was previously explained in section 14 "Creating an Example Linux Kernel Module"

16.4.1 Register Kernel Module for Debugging

We need to register the kernel modules we are interested in debugging with the debugger. This is done using the *debugKernelModule* command. The command has been added into the tcl command space of the debugger under the debugger namespace and so is accessed through the tcl command window. This can be done from the debug window by prefixing the command with the keyword 'tcl' or the tcl global namespace prefix '::'.

```
tcl lkmbreakonload -module led_drv
```

or

```
::lkmbreakonload -module led_drv
```

⇒ The command has two arguments: the module name and the file containing the module. If the file argument is omitted it is assumed the file is called <module name>.ko.

16.4.2 Installing the Kernel Module

Here we will look at what happens now when we install the led_drv kernel module example in the guest linux operating simulation.

Use the same commands as previously used to install the kernel module when logged in as root in the guest operating system.

```
mknod /dev/led c 42 0
chmod 666 /dev/led
insmod led_drv.ko
```

This time the insmod command does not return to the prompt. This is because the debugger has detected the loading of the kernel module led_drv that was previously registered for debugging and stopped the simulation. You will notice also that the symbol table is generated.

```
idebug (mipsle1) > c
add symbol table from file "led_drv.ko" at
    .text_addr = 0xc0039000
    __ksymtab_addr = 0x0
Breakpoint 4 at *0xc0039184 triggered for processor mipsle1
led_init () at /home/graham/playground/kernelModule/ledDriver/ledDrvModule/led_drv.c:117
117 {
idebug (mipsle1) > list
112
113     /*
114     * Initialize the driver - Register the character device
115     */
116     static int led_init (void)
117     {
118         int ret;
119
120         printk ("LED driver: hello\n") ;
121         ret = register_chrdev (LED_MAJOR, DEVICE_NAME, &ops);
idebug (mipsle1) > █
```

We have stopped at the start of the init function. We are now able to debug the init function and also add breakpoints to other functions of interest, watchpoints on variables etc

16.4.3 Adding Breakpoints

The example application that uses the led_drv driver module writes values to the LED. We can apply a breakpoint on the led_write function in the driver to debug this

```
idebug (mips1e1) > b led_write
Created breakpoint 5 at 0xc00390f0: file /home/graham/playground/kernelModule/ledDriver/ledDrvModule/led_drv.c, line 102
idebug (mips1e1) > _
```

We can use all the standard debug features to debug the kernel module, for example breakpoints, watchpoints, single stepping, examining registers etc.

16.4.4 Source Level Debug

We are able to debug the kernel driver at source level.

When we continue the simulation with the breakpoint set on led_write, we hit a breakpoint as soon as the led_flash.exe test application is executed.

```
Breakpoint 5 at led_write triggered for processor mips1e1
led_write (file=0x811aba40, buffer=0x811aba40 "\367c\207\220h\354\207 \337\022\201\024\004\254\206\260\231\003
, length=1, offset=0x8641bf18) at /home/graham/playground/kernelModule/ledDriver/ledDrvModule/led_drv.c:102
102     printk ("led_write\n");
idebug (mips1e1) > list
97         loff_t * offset)        /* offset in the file */
98     {
99         unsigned char c;
100         //      int ret;
101
102         printk ("led_write\n");
103         if (get_user (c, buffer) != 0)
104             return -EFAULT;
105         printk ("led_write: %x\n", (unsigned int)c);
106         *(char *)LED_REG = c;
idebug (mips1e1) > _
```

17 Restrictions and Caveats

The platform is tested only under the following conditions:

- Little endian memory organization
- Debian distribution of Linux kernel version 2.6.23.11

APPENDIX A

A.1 Platform Command Line Arguments

Argument	Parameter	Description
P	integer	expose a port on which a debugger can be attached
T	integer	start tracing after integer number of instructions have been performed by the MIPS processor
initrd	none	boot using the initial ramdisk
finishonhalt	none	cause the simulation to be stopped when a soft reset is requested during the halt operation
wallclock	none	Simulate using wall clock time i.e. simulation will not run faster than real time
redir	none	redirection of tcp ports to allow tcp connection with another machine for file transfers etc redirection string is tcp:15901:10.0.2.15:5901,tcp:11001:10.0.2.15:11001
tftp	String	Enable the emulated TFTP server and specify the root directory in the host machine
stopafter	double	stop execution after an integer number of instructions has been performed on the MIPS processor.
nographics	none	do not use SDL for the output graphics
variant	string	define the MIPS32 processor variant to be modeled, for example 4KEc, 24K etc
bootimage	none	define the boot loader file to be loaded and used.

APPENDIX B

B.1 Some Terms Explained

Term	Description
Guest Operating System	Is the operating system that is running within the simulation
Host Operating System	Is the OS of the Host machine being used
LKM	Linux Kernel Module
Kernel Module	A kernel extension 'driver' that executes as part of the kernel, often dynamically loaded
