8.2 Net Ports	9
8.3 Bus master ports	9
8.4 Bus slave ports	9
8.5 Packetnets	9
9.0 More information (documentation) on peripheral models and modeling	

## 1.0 Model Specific Information

This document provides usage information for an Imperas OVP peripheral behavioral model.

The document is split into sections providing specific information for this peripheral, including any ports for connecting into a platform, registers, other component parts, and configuration options and general information for peripheral modeling with Imperas OVP.

#### 1.1 Description

This model contains an accurate Register set interface. The functionality has only been implemented to sufficiently boot uClinux for more information visit http://www.atmel.com/products/at91

#### 1.2 Licensing

Open Source Apache 2.0

#### 1.3 Limitations

This model is sufficient to boot Linux

#### 1.4 Reference

Rev. 1354D ARM08/02

#### 1.5 Location

The PowerSaving peripheral model is located in an Imperas/OVP installation at the VLNV: atmel.ovpworld.org / peripheral / PowerSaving / 1.0.

#### 2.0 Bus Slave Ports

This model has the following bus slave ports:

#### 2.1 Bus Slave Port: bp1

Table 1. Bus Slave Port: bp1

Name	Size (bytes)	Must Be Connected	Description
bp1	0x4000	T (True)	

#### Table 2. Bus Slave Port: bp1 Registers:

Name	Offset	Width (bits)	Description	R/W	is Volatile
REG_PS_CR	0x0	32			
REG_PS_PCER	0x4	32			
REG_PS_PCDR	0x8	32			
REG_PS_PCSR	0xc	32			

# 3.0 Platforms that use this peripheral component

Peripheral components can be used in many different platforms, including those developed by Imperas or by

Copyright (c) 2021 Imperas Software Limited www.imperas.com

OVP License. Release 20210408.0

other users of OVP. You can use this peripheral in your own platforms.

### 5.0 General Information on Peripheral Models

This document provides usage information for an Imperas OVP peripheral behavioral model.

The document is split into sections providing specific information for this peripheral, including any ports for connecting into a platform, registers etc. and configuration options and general information for peripheral modeling with Imperas OVP.

#### 5.1 Background

Imperas OVP simulation technology enables very high performance simulation, debug and analysis of platforms containing multiple processors and peripheral models. The technology is designed to be extensible: you can create new models of processors, peripherals and other platform components using interfaces and libraries defined by OVP.

The peripheral models created using the OVP APIs run on the Peripheral Simulation Engine (PSE).

The model is typically written in C and compiled into an executable for the PSE processor architecture. The model is compiled for speed of execution and to protect IP. It is dynamically loaded by the simulator at run time.

# 6.0 Building peripherals easily with Imperas iGen

To aid with model creation, Imperas products include iGen, a model generation tool. iGen takes the laborious and error-prone task of constructing the various hardware model and software element files required for a typical model, and automates this process. iGen creates the needed C files. iGen also creates the C++ SystemC TLM2 interface files needed to run peripheral models in SystemC simulations.

iGen takes as input a simple script specification that includes device internals such as registers and memories, port information, component descriptors, and other elements. iGen then builds the C code model files and user editable templates. These include model frameworks with registers, function calls, memory map, and other items. It ensures that all component parts of the model are well-structured using best practices, and are consistent throughout the files, thus eliminating a common source of errors.

More information on iGen can be found: <a href="mailto:imperas.com/products">imperas.com/products</a>.

# 7.0 Peripheral model internals

Each instance of a peripheral model runs on its own virtual machine with an address space large enough for the model. This processor (the PSE) and its memory are separate from any processors, memories and buses in the platform being simulated; they exist only to execute the code of the peripheral model.

Interception of functions defined in the peripheral model allows the use of features of the host system in the

implementation of the behavior of a peripheral. As an example, a real platform might contain a video display device. When simulating this system, it is generally more convenient not to simulate the complete video display device but to use a video package available on the host machine, such as SDL, and to use this to render to the host display. Also models of uarts, ethernet devices and USB components can make use of the host PC resources during simulation, to allow, for example, a simulation to browse the real internet, or the simulation to connect to a real USB device.

# 8.0 Parts of peripheral models

#### 8.1 Configuring the Peripheral Instance with Parameters

A peripheral can include the behaviour of several configurations. These are controlled when the peripheral is instanced in the platform by setting parameters defined on the peripheral.

#### 8.2 Net Ports

Peripherals may be connected to other peripherals or processors with signal wires (nets). These can be used to act as interrupt signals or used to control behavior between peripherals.

The wires are created in the platform as nets and this net is connected into the peripheral using a net port.

#### 8.3 Bus master ports

A bus master port initiates (and controls the address of) a bus cycle. Bus cycles are generated by behavioral code within the peripheral model.

#### 8.4 Bus slave ports

A peripheral can be defined as having several bus slave ports. The bus slave ports can be split into several address blocks. Each address block be either local memory or memory mapped registers. Both of these can have associated callback functions. A memory mapped register can also be defined as specific read/write access, whether it is volatile, and also whether it is associated with a reset pin and mask. A memory mapped register can also have specific bit fields defined.

#### 8.5 Packetnets

A peripheral can be defined as being connected to packetnet ports. A packetnet is used to model packet based communication such as Ethernet, CAN bus or GSM. A packetnet is created in a platform, then connected to packetnet ports on model instances. A packetnet can have many connections, each able to send or receive packets. A packetnet is used as an efficient method of communication within OVP models.

For more information on modeling with packetnets, please see the peripheral modeling documentation: OVP\_Peripheral\_Modeling\_Guide.pdf, OVPsim\_and\_CpuManager\_User\_Guide.pdf and the example: \$IMPERAS\_HOME/Examples/Models/Peripherals/packetnet.

## 9.0 More information (documentation) on peripheral models and modeling

More information on modeling and APIs can be found at: <a href="https://overld.org/technology\_apis">OVPworld.org/technology\_apis</a>.
